The demonstration of a quasi-two-dimensional electron gas (2DEG) in $\text{LaAlO}_3/\text{SrTiO}_3$ heterostructures has stimulated intense research activity in recent years. The 2DEG has unique properties that are promising for applications in all-oxide electronic devices. For such applications it is desirable to have the ability to control 2DEG properties by external stimulus. Here, based on first-principles calculations we predict that all-oxide heterostructures incorporating ferroelectric constituents, such as $\text{KNbO}_3/\text{ATiO}_3$ ($A = \text{Sr}, \text{Ba}, \text{Pb}$), allow creating a 2DEG switchable between two conduction states by ferroelectric polarization reversal. The effect occurs due to the screening charge at the interface that counteracts the depolarizing electric field and depends on polarization orientation. The proposed concept of ferroelectrically controlled interface conductivity offers the possibility to design novel electronic devices.

Advances in thin-film deposition and characterization techniques have made possible the experimental realization of oxide heterostructures with atomically abrupt interfaces. The development of such heterostructures is very promising as it offers novel functionalities and device concepts. In particular, the recent discovery of a quasi-two-dimensional electron gas (2DEG) at the interface between two oxide insulators, SrTiO_3 and LaAlO_3 , has attracted significant attention [1–5]. It was demonstrated that the 2DEG has high carrier mobility and electron density, which makes it interesting for applications in all-oxide field-effect devices similar to that based on modulation doping of III–V semiconductors [6]. It was also found that at low temperatures the 2DEG could become magnetic [7] or superconducting [8].

Electronic reconstruction is considered to be the primary mechanism responsible for the formation of 2DEG. Perovskite oxides have chemical formula $A^X B^Y O_3$ (where $X + Y = 6$) and along the [001] direction consist of alternating planes of $A^X O_2^-$ and $B^Y O_2^{2-}$, which can be charged or neutral. For example, LaAlO_3 consists of alternating $(\text{LaO})^+$ and $(\text{AlO}_2)^-$ charged planes and SrTiO_3 consists of alternating $(\text{SrO})^0$ and $(\text{TiO}_2)^0$ neutral planes. When LaAlO_3 is deposited on top of SrTiO_3 , the polar discontinuity at the interface leads to the divergence of the electrostatic potential with the increasing number of LaAlO_3 unit cells. To avoid this divergence half an electron per two-dimensional unit cell is transferred across the interface from LaAlO_3 to SrTiO_3 , causing the LaO/TiO_2 interface in the $\text{LaAlO}_3/\text{SrTiO}_3$ (001) heterostructure to be conducting [2]. Oxygen vacancies created during the growth of oxide heterostructures play an important role in contributing to high sheet conductivities [3–5]. There is, however, experimental evidence that under sufficiently high oxygen pressure electronic reconstruction becomes the dominant effect [2].

Analogous to the ionic polar discontinuity, the 2DEG may be created at an interface due to electric polarization discontinuity. This has been observed in $\text{ZnO}/\text{Mg}_x\text{Zn}_{1-x}\text{O}$ heterostructures where a sheet charge is formed at the interface to relax the electrostatically unfavorable state [9]. An interesting possibility is to combine the two discontinuities at the interface by using a ferroelectric oxide material as one (or both) constituents of the 2DEG heterostructure. Because of reversible polarization of the ferroelectric, such a functional interface may be served to control the 2DEG properties by ferroelectric polarization switching, which is very interesting for applications in nanoelectronics.

In this Letter, based on first-principles band structure calculations, we demonstrate the possibility to create a switchable 2DEG at oxide interfaces composed of perovskite ferroelectrics. As a representative model, we consider $\text{KNbO}_3/\text{SrTiO}_3$ (001) heterostructures with abrupt NbO_2/SrO interfaces. KNbO_3 is a ferroelectric material that consists of alternating planes of $(\text{NbO}_2)^+$ and $(\text{KO})^-$ along the [001] direction, which are analogous to the polar planes in the LaAlO_3 . Therefore, the polar discontinuity at the $(\text{NbO}_2)^+ / (\text{SrO})^0$ interface in $\text{KNbO}_3/\text{SrTiO}_3$ (Fig. 1) is similar to that at $(\text{LaO})^+ / (\text{TiO}_2)^0$ interface in $\text{LaAlO}_3/\text{SrTiO}_3$. We predict, therefore, the formation of 2DEG at the NbO_2/SrO interface. We show that electronic

FIG. 1 (color online). Atomic structure of the NbO_2/SrO interface in $\text{KNbO}_3/\text{BaTiO}_3$ (001) heterostructure.

properties of the 2DEG are affected by the spontaneous polarization of ferroelectric KNbO₃ due to the formation of the screening charge at the interface, counteracting the polarization charge and the depolarizing electric field. The screening charge depends on polarization orientation and consequently 2DEG can be switched between two conduction states by polarization reversal. We predict that a similar phenomenon occurs at full ferroelectric KNbO₃/BaTiO₃ and KNbO₃/PbTiO₃ oxide interfaces and infer a possibility of controllable metal-insulator transition at the interface.

First, we study the effect of ferroelectric polarization reversal on electronic properties of the NbO₂/SrO interface in the KNbO₃/SrTiO₃ (001) heterostructures. Figure 1 shows the interface structure of the system. We perform density-functional calculations [10] using the projector augmented wave [11] method implemented within the Vienna *ab initio* simulation package (VASP) [12,13]. We use periodic boundary conditions and we build up a (KNbO₃)_m/(SrTiO₃)_n superlattice that contains $m = 8.5$ unit cells of KNbO₃ and $n = 7.5$ unit cells of SrTiO₃ along the [001] direction [14]. This geometry allows us to study the effect of polarization reversal in a single heterostructure by comparing properties of the two interfaces. The in-plane lattice constant of the superlattice is fixed to the experimental lattice constant of SrTiO₃ ($a = 3.905$ Å). The out-of-plane lattice constant of bulk SrTiO₃ and KNbO₃ are obtained by minimizing the total energy. Subsequently, the interface separation distance is determined by minimizing the total energy of the (KNbO₃)_m/(SrTiO₃)_n superlattice keeping the in-plane lattice constant and out-of-plane separation in KNbO₃ and SrTiO₃ subunits fixed.

In order to reveal the presence of 2DEG we, first, consider the KNbO₃/SrTiO₃ interface assuming that KNbO₃ is in paraelectric state. For this purpose we impose mirror plane symmetry at the central NbO₂ monolayer and minimize the total energy of the whole system [15]. Figure 2(a) shows the density of states (DOS) projected onto the 4d orbitals of Nb atoms, located at different monolayers l away from the interface. It is seen that there are occupied states at and below the Fermi energy (E_F). The electron density decreases with the distance from the interface which suggests the formation of the n -type 2DEG at the interface. A similar behavior is obtained for the Ti-3d states (Fig. 2(b)), though with a lower DOS compared to the Nb-4d states. We find that the total charge transferred to the interface is $0.5e$ per unit cell. This behavior is similar to that found previously for the LaO/TiO₂ interface in LaAlO₃/SrTiO₃ heterostructures [16–19].

Next we relax the constraint of reflection symmetry and minimize the total energy with respect to atomic coordinates of all the atoms in the heterostructure. This produces a ferroelectric state of KNbO₃. We find that ferroelectric displacements in the central monolayers of KNbO₃ are close to those found in the bulk KNbO₃ that are constrained

FIG. 2 (color online). Density of states (DOS) projected onto Nb-4d states (a) and Ti-3d states (b) located at different monolayers l away from the NbO₂/SrO interface for paraelectric state of (KNbO₃)_{8.5}/(SrTiO₃)_{7.5} superlattice. The shaded plots are the DOS of atoms in the central monolayer of KNbO₃ (a) and SrTiO₃ (b). The vertical line denotes the Fermi energy (E_F).

to have the in-plane lattice constant $a = 3.905$ Å. We calculate the polarization using the Berry phase method [20] and find $P_{\text{KNbO}_3} = 0.41$ C/m². We also find polar displacements in SrTiO₃ and estimate an induced polarization in the SrTiO₃ layer to be $P_{\text{SrTiO}_3} = 0.17$ C/m². The energy difference between the paraelectric and ferroelectric states of KNbO₃ is about 66 meV per unit cell in the superlattice compared to 73 meV in the bulk. This indicates that the stability of the ferroelectric state in the heterostructure is similar to that of the bulk.

In the ferroelectric state the two interfaces are no longer equivalent and are distinguished by the orientation of the ferroelectric polarization with respect to them. Here and below we assume that polarization of KNbO₃ is oriented from left to right and designate these interfaces as “left” for the KNbO₃ polarization pointing away from the interface and “right” for the KNbO₃ polarization pointing toward the interface, as is indicated in the top panel of Fig. 3. Because of the presence of polarization the electronic properties of the two interfaces are different. This is evident from Fig. 3(a) which shows the averaged DOS at the left and right interfaces in the vicinity of the Fermi energy. It is seen that there is a significant contrast in the DOS and the number of occupied states at the two interfaces distinguished by polarization orientation. Table I shows the number of the occupied Nb-4d and Ti-3d states, which is calculated by summing up the respective local DOS on all the atoms from the middle monolayer up to the left (right) interface integrated from the conduction band minimum up to the Fermi energy. It is seen that the occupancy of both the Nb-4d states and Ti-3d states is enhanced significantly at the right interface as compared to the left interface due the presence of ferroelectric polarization in KNbO₃. This suggests that carrier density of 2DEG at the interface may be controlled by switching the polarization.

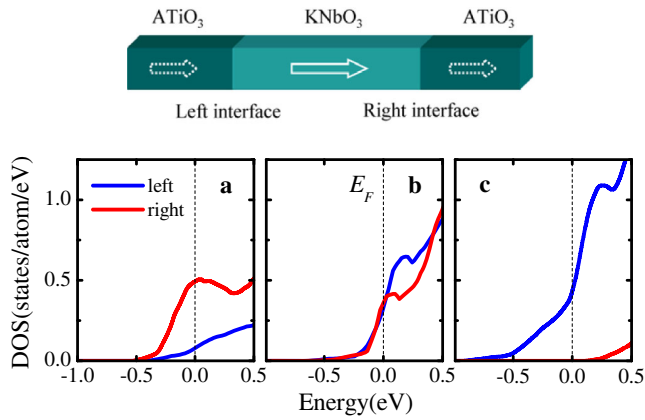

FIG. 3 (color online). DOS near the Fermi energy (E_F) averaged over four Nb and three Ti atoms at the left and right NbO₂/AO interfaces in (KNbO₃)_{8.5}/(ATiO₃)_{7.5} superlattices for $A = \text{Sr}$ (a), $A = \text{Ba}$ (b), and $A = \text{Pb}$ (c). The top panel shows schematically geometry of the unit cell with polarization indicated by arrows.

The physical mechanism responsible for this behavior is screening of the polarization charge which occurs through the change in the free electron density of 2DEG at the interface. The presence of screening can be seen from the comparison of the number of free carriers accumulated at the two interfaces in paraelectric and ferroelectric states of KNbO₃/SrTiO₃. We calculate local charges using Wigner-Seitz (WS) spheres, as specified by VASP. We find that in the paraelectric state the number of free electrons is 0.29 per interface area of the unit cell at both interfaces, whereas in the ferroelectric state the corresponding values are 0.15 and 0.43 at the left and right interfaces, respectively (see Table I). This implies that due to ferroelectricity of KNbO₃ extra 0.14 electrons are accumulated at the right interface and 0.14 electrons are removed from the left interface. Evidently the induced screening change has an opposite sign to the polarization charge, thereby counteracting the depolarizing electric field. Figure 4 (circles) shows the screening charge distribution across the unit cell of KNbO₃/SrTiO₃, indicating its localization near the interfaces.

The change in the density of the 2DEG in going from paraelectric to ferroelectric KNbO₃ can be understood from simple electrostatic considerations. As shown above, for the paraelectric state the 2DEG density at the two interfaces is the same due to the identical polar discontinuity. The ferroelectric state introduces polarization

TABLE I. Number of electrons projected on Nb and Ti atoms per interface area of the unit cell.

| Heterostructure | Right interface | | | Left interface | | |
|---------------------------------------|-----------------|------|-------|----------------|------|-------|
| | Nb | Ti | Total | Nb | Ti | Total |
| KNbO ₃ /SrTiO ₃ | 0.36 | 0.07 | 0.43 | 0.09 | 0.06 | 0.15 |
| KNbO ₃ /BaTiO ₃ | 0.25 | 0.03 | 0.28 | 0.12 | 0.15 | 0.27 |
| KNbO ₃ /PbTiO ₃ | 0.00 | 0.00 | 0.00 | 0.25 | 0.47 | 0.72 |

charges of opposite sign at the two interfaces. This results in enhancing the polar mismatch at one interface while lowering it at the other interface which leads to a corresponding increase and decrease in the free charge density of the 2DEG at the two interfaces.

To make this statement quantitative we estimate the interface polarization charge density σ_p from the difference of the polarizations in KNbO₃ and SrTiO₃. This gives the polarization charge per unit cell area of $\sigma_p = 0.23e$. The WS charge per unit cell at the two interfaces changes by $0.14e$ in going from paraelectric to ferroelectric state. However, the WS charge ($0.29e$) underestimates the actual charge ($0.5e$) in the paraelectric state. When scaled with the factor $0.5/0.29$, the change in charge at either interface becomes $0.24e$, which is about the same as the polarization charge. Thus, we conclude that polarization charge screening is the mechanism responsible for the change in the 2DEG carrier density.

The predicted effect of ferroelectric polarization on electronic properties of 2DEG at oxide interfaces is further elaborated by performing calculations for all-ferroelectric (KNbO₃)_{8.5}/(BaTiO₃)_{7.5} and (KNbO₃)_{8.5}/(PbTiO₃)_{7.5} heterostructures. For both systems we find that the presence of polar interfaces leads to the formation of 2DEG. However, the response of 2DEG on polarization switching is different depending on the magnitudes of ferroelectric polarization in layers comprising heterostructures.

For the KNbO₃/BaTiO₃ system, the polarization of strained BaTiO₃ is similar in magnitude to the polarization of strained KNbO₃. This leads to the almost cancellation of the effect of polarization on polar discontinuity at the two interfaces. This results in the reduced asymmetry of the DOS near the two interfaces, as is seen from Fig. 3(b). Figure 4 (squares) and Table I indicate that the reversal of

FIG. 4 (color online). Screening charge distribution across the unit cell of (KNbO₃)_{8.5}/(ATiO₃)_{7.5} superlattices for $A = \text{Sr}$ (circles), $A = \text{Ba}$ (squares), and $A = \text{Pb}$ (triangles). The screening charge is obtained by calculating the difference in electron density on Nb and Ti atoms for ferroelectric and paraelectric states by integrating DOS from the conduction band minimum up to Fermi energy. The direction of polarization is from left to right.

ferroelectric polarization is accompanied by the change in the occupation of the Nb-4*d* and Ti-3*d* states, but the total number of occupied states remains almost unchanged.

For the KNbO₃/PbTiO₃ system, the polarization of the strained PbTiO₃ exceeds significantly the polarization of KNbO₃. This leads to a larger occupation number and the DOS at the left interface as compared to the right interface [see Fig. 3(c)], which is opposite to the case of KNbO₃/SrTiO₃ system [Fig. 3(a)]. Moreover, the polarization charge is so big (about 0.58*e* per unit cell area) that the existing free charge at the interfaces does not fully compensate it. All the free charge is transferred from the right to the left interface making the right interface insulating, as is seen from both Fig. 3(a) and Table I. Thus, the reversal of ferroelectric polarization in KNbO₃/PbTiO₃ heterostructure leads to a metal-insulator phase transition at the interface. We note that this result is based on the generalized gradient approximation (GGA) which is known to overestimate the polarization of PbTiO₃ (see, e.g., Ref. [21]). This fact does not affect, however, the very general conclusion of our calculations about the dependence of the 2DEG properties on the relative values of the electric polarization of the two constituents forming 2DEG [22].

In conclusion, based on first-principles calculations we have predicted the possibility to create a 2DEG in all-oxide heterostructures incorporating ferroelectric constituents, KNbO₃/ATiO₃ (*A* = Sr, Ba, Pb). We showed that the 2DEG is switchable between two conduction states as controlled by ferroelectric polarization orientation. This effect depends on the contrast between polarizations of the two constituents of the heterostructure: the larger is the difference in the two polarizations, the bigger is the effect. For sufficiently large polarization divergence at the interface, we predict a metal-insulator phase transition driven by polarization reversal. Experimentally, the proposed concept of ferroelectrically controlled interface conductivity could be realized, e.g., in a KNbO₃/ATiO₃ device by incorporating a gate electrode to switch the ferroelectric polarization by applied bias voltage. This concept may be very interesting for memory and logic applications, and we hope that our predictions will stimulate experimental studies in this field.
