This Article is brought to you for free and open access by the Research Papers in Physics and Astronomy at DigitalCommons@University of Nebraska - Lincoln. It has been accepted for inclusion in Peter Dowben Publications by an authorized administrator of DigitalCommons@University of Nebraska - Lincoln.
Deposition of a boron nitride film is carried out by introducing decaborane and dry nitrogen or ammonia into a plasma-assisted chemical vapor deposition chamber. The nitrogen or ammonia partial pressure should provide an excess over the decarborane pressures for example 200 milliTorr of N₂ or NH₃ and 50 MilliTorr of B₁₀H₁₄. Other film layers can also be produced starting from decaborane.
DEPOSITION OF BORON-CONTAINING FILMS FROM DECABORANE

BACKGROUND OF THE INVENTION

This invention relates to a process for deposition of films of boron nitrides or other binary boron films, such as boron phosphide, boron carbide, boron silicide, boron arsenide, etc. as well as to the deposition and subsequent doping of boron. The invention is more particularly directed to deposition, such as by plasma assisted deposition of BN films or the like from a mixture of decaborane and another gas such as nitrogen, ammonia, methane, silane, etc. to combine with boron in the film. Boron nitride is useful in many applications, and particularly in semiconductor electronics, because of its high resistivity, insulating, and dielectric properties. Desirably, boron nitride should be deposited in cubic form which is similar to the diamond lattice structure of silicon, gallium arsenide, or zinc sulfide. Boron nitride coatings are also useful as corrosion resistant, dielectric, and insulating coatings in a number of applications. Boron carbide, boron phosphide, boron arsenide, and other binary layers based on boron and another element each have particular utilities which are well known and documented.

Several previous processes for depositing boron nitride films are described, for example, in U.S. Pat. Nos. 4,714,625; 4,656,052; 4,622,236; 4,412,899; 4,415,420; 4,297,387; 3,692,566; 3,499,799; and 3,152,066. Other processes employing insulation, barriers, or resistors. Such a technique is a further object of this invention.

In this invention decaborane and another gas such as nitrogen, In addition to BN coatings, this technique can be used for depositing cubic BN, the respective partial pressures for nitrogen and decaborane can be 200 micros (200 milliTorr) and 50 micros (50 milliTorr). Because of the inherent stability of the decaborane as compared with other boron compounds, such as diborane (B2H6), photolytic and pyrolytic deposition is possible permitting boron nitride film to be deposited in coatings with very small, highly precise spatial resolution. This opens the door to BN or BN coating applications not possible with diborane.

In addition to BN coatings, this technique can be used for depositing cubic BN, boron phosphide, boron silicide, boron germanide, and/or boron arsenide films, starting with decaborane admixed with gases such as methane (CH4), phosphane (PH3), silane (SiH4), germane (GeH4) and arsane (AsH3), for example. Other gases such as higher carbon alkanes, ethylene, silol, etc., can also be employed.

Pure boron can also be deposited, for example by irradiating the substrate in the presence of decaborane with ultraviolet photons in the wavelength range of 200 nm to 522 nm. Boron can be deposited this way as a dopant on N-type semiconductor material to create a PN junction with precisely controlled geometry. This technique permits the boron-doped region to be dimensioned as small as 20 microns across.

The above and many other objects, features, and advantages of this invention will be more fully understood from the ensuing description of one embodiment of the invention, with reference to the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWING

The sole FIGURE of Drawing is a schematic view of a plasma reactor in which the process of this invention is carried out according to one embodiment of the invention.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

With reference to the sole drawing FIGURE, a plasma assisted chemical vapor deposition (PACVD) chamber 10 is here comprised of a flanged cross 12 having upper and lower vertical arms, horizontal arms, and flange plates, and seal rings, as is generally practiced. An upper pedestal 14 depends within a vertical arm to a substrate-retaining plate 16 which holds a substrate 18 to be coated e.g., with a cubic boron nitride deposition. The plate 16 can include a cartridge heater. The plate 16 here serves as cathode. Another pedestal 20 rises within the lower arm and supports a plate 22 that serves as anode. A standard radio-frequency generator unit 24 applies an r.f. current to the plates 16 and 22, with a 90 volt d.c. bias. Here the unit 24 has a frequency of 13.56 kHz and an output power of 20 watts, as is standard. A gas inlet supply tube 26 injects reaction gases through one horizontal arm of the cross 12, while a reactor gauge outlet tube 28 and a vacuum line 30 are coupled to the opposite horizontal arm. The line 30 is connected to a vacuum pump, not shown. A gas source 32, here a tank of N2 is coupled through a regulator 34 to the inlet tube 26, and a container 36 of decaborane, with a suitable pressure regulator 38, is likewise coupled to the tube 26. The regulators 34 and 38 are suitably controlled so that the nitrogen gas and decaborane
vapor are introduced into the reactor at respective partial pressures of about 200×10⁻³ mm Hg (200 milliTorr) and 50×10⁻³ mm Hg (50 milliTorr). To produce cubic BN, it is necessary that there be an excess of the gaseous mixture of decaborane and another gas relative to the decaborane gas.

The resulting BN coating can be applied uniformly on the substrate or, for example, can be applied in patterns using a direct writing technique. The BN film or coating can provide a hard, protective coat for semiconductor devices or integrated circuits. Also, because of the favorable insulating properties and thermal expansion coefficient, boron nitride can be used as an insulating layer for separating active semiconducting nitride film on said substrate.

**EXAMPLE I**

A PACVD chamber containing a silicon substrate was maintained at a chamber pressure of 7.2 microns. An outgas rate of 0.5 per minute was observed. This cartridge heater associated with the substrate retaining plate was turned on and a standard RF voltage of 13.56 KHz and 20 watts was applied. Dry nitrogen was introduced at a pressure of 300 microns, while decaborane was introduced at a pressure of 20 microns. The pressure was permitted to stabilize and plasma deposition took place for a period of about four-and-one-half hours. Then, the temperature was gradually reduced and the reactor was purged with dry nitrogen.

The above process was repeated with several sample substrates for different periods. The resulting boron nitride films were found to be uniform and an opaque whitish color. The thickness of the coating could be varied in a range of at least 50 nanometers to 25 microns. The films had a hydrogen content no greater than 6.6%, which is far better than 13 to 16% obtained in other deposition methods.

Similar results were found when ammonia, rather than nitrogen, was used as the gas that mixed with decaborane. In all cases, hydrogen content of the film was no more than about 6.6 percent.

**EXAMPLE II**

Pure decaborane gas was introduced into a reactor containing a silicon substrate. A pattern of closely spaced dots was illuminated onto the substrate using ultraviolet light of a wavelength of 300 nm. The reactor was purged with dry nitrogen, and the substrate removed and analyzed with a scanning electron microscope. In this case, islands of pure boron were deposited at a desired thickness of about 10 microns, and with a diameter of substantially 20 microns. Deposition of boron outside these islands appeared to be insignificant. The hydrogen content was about 6.6 percent.

While the invention has been described here with reference to one preferred embodiment, it should be recognized that the invention is not delimited by that embodiment, which is offered as an example. Rather, many modifications and variations would present themselves to those skilled in the art without departing from the scope and spirit of this invention, as defined in the appended claims.

What is claimed is:

1. A process for depositing a boron nitride film onto a suitable substrate comprising:
   - supplying into a chamber that contains the substrate a gaseous mixture of decaborane and a nitrogen-based gas whose molecules contain at least one nitrogen atom, wherein said nitrogen-based gas is provided at a partial pressure that is several times as high as the partial pressure of said decaborane, and
   - energizing the gaseous mixture in the chamber sufficiently to dissociate the nitrogen atoms from said molecules and to dissociate boron atoms from the decaborane, which then combine as said boron nitride film on said substrate.
   - The process of claim 1 wherein said nitrogen-based gas is selected from the group that consists of N₂, NH₃ and mixtures thereof.
   - The process of claim 1 wherein said nitrogen-based gas and said decaborane are supplied at partial pressure of approximately 200 and 50 milliTorr, respectively.
   - The process of claim 1 wherein said chamber is an RF plasma reactor and said energizing is carried out by applying an RF current to the chamber while supplying said gaseous mixture thereto.
   - A process for depositing a binary film of boron and one other element onto a suitable substrate, comprising supplying into a chamber that contains the substrate a gaseous mixture of decaborane and another gas whose molecules contain at least one atom of said other element, wherein said other gas is provided at a partial pressure that is several times as high as the partial pressure of said decaborane, and energizing said gaseous mixture in the chamber sufficiently to dissociate said atoms from said molecules and to dissociate said boron atoms from the decaborane, which combine as said binary film on said substrate.
   - The process of claim 5 wherein said other gas is selected from the group consisting of N₂, NH₃, PH₃ and AsH₃.
   - The process of claim 5 wherein said other gas is selected from the group consisting of ketanes, silane, and germane.
   - A process for depositing a boron film onto a suitable substrate, comprising introducing into a chamber that contains said substrate decaborane gas, and energizing said decaborane gas at selected locations on said substrate sufficiently to dissociate the boron from the decaborane which deposits itself on said substrate at said selected locations.
   - The process of claim 8 wherein said energizing includes illuminating a predetermined pattern on said substrate using ultraviolet radiation.
   - The process of claim 1 wherein said energizing is carried out photolytically using direct writing on said substrate.
   - The process of claim 8 wherein said energizing is carried out photolytically using direct writing on said substrate.
   - The process of claim 8 wherein said suitable substrate is an N-type semiconductor and said boron that is deposited at said selected locations is effective as a dopant to create P-type regions therein.
