Abstract: Quasi monoenergetic and tunable x-ray beams are reported by inverse-Compton scattering from laser wakefield accelerated electrons. The high peak brightness, ultrashort duration, and small size of the source make it uniquely suitable for many applications.

OCIS codes: (140.7090) Ultrafast lasers; (290.3200) Inverse scattering; (350.5610) Radiation

Synchrotron x-ray sources play a critical role in the advancement of science and technology. However, the breadth of applications suitable for conventional radio-frequency-based synchrotron sources is limited by the size and cost of such devices. Several schemes, many of which are based on lasers[1], have been recently developed in order to create a compact and affordable source of x-rays.

Inverse-Compton scattered x-ray beams produced from laser wakefield accelerated (LWFA) e-beams have been of particular interest because of the ultrashort duration, high peak brightness, and high energy of such sources. They also benefit from intrinsic synchronization of the e-beam and scattering laser because the LWFA drive laser pulse and scattering laser pulse originate from the same laser beam. While these all-optical sources have many benefits, the spectra of the x-rays reported in previous experiments have been polychromatic[2–5]. We have now achieved x-rays with a quasi monoenergetic spectrum[6]. In addition, the central energy of the beams can be tuned over more than an order of magnitude from 60 keV to above 1 MeV. These characteristics make the x-ray beam more useful for a broad range of applications.

The x-ray beams were produced using the 100-TW Diocles laser system at the Extreme Light Laboratory. The laser beam was split into two pulses by a beamsplitter. The first pulse, with 1.3-1.7 J of energy and 33 fs duration, was used to drive a laser wakefield produced using a dual-nozzle gas jet. The gas jet design limited the electron-injection region and allowed injection and acceleration to be independently controlled resulting in a tunable, quasi-monoenergetic electron beam. The second pulse, with 0.13-0.17 J of energy and 150 fs duration, was focused and scattered off of the accelerated electrons, acting as an optical undulator. The e-beam and scattering laser beam were overlapped 1.5 mm after the accelerator at an angle of 170°, as shown in Fig. 1.

The x-ray spectral distribution, measured using Ross filter pairs, indicates a spectrum with a 66±7 keV central energy and ~50% FWHM energy spread. The numerically predicted results, simulated from the measured laser and e-beam characteristics, is shown in Fig. 2. These results are in good agreement with the measured results both in terms of central energy and energy spread, 64 keV and 50% FWHM, respectively.
The x-ray central energy was tuned from $\sim$60 keV – 1 MeV by tuning the e-beam energy. The central energy of the higher energy x-rays was measured using a separate set of x-ray transmission filters. Assuming an x-ray energy distribution based on the measured e-beam spectrum, the x-ray central energy was determined to follow a $4\gamma^2$ scaling, where $\gamma$ is the relativistic Lorentz factor obtained from the e-beam central energy. The x-ray peak spectral brightness was $\sim$3x10$^{18}$ s$^{-1}$mm$^{-2}$mrad$^{-2}$ (per 0.1% bandwidth) for 70 keV beams and $\sim$1x10$^{19}$ s$^{-1}$mm$^{-2}$mrad$^{-2}$ (per 0.1% bandwidth) for 1 MeV beams.

Fig. 2. X-ray spectral intensity simulated from measured LWFA e-beam

X-rays were produced for more than 93% of the laser shots with a photon number stable to within 60% of the average measured value, 1.7 x 10$^6$. The instability was primarily due to fluctuations in the e-beam charge. The e-beam energy spectrum was quasi monoenergetic over the entire tuning range. Based on measurements of the energy spectrum of the electron beam, 56% of the x-ray beams, over the entire range of tunability, had an energy spread of $\leq$50%.

This proof of principle experiment opens up exciting possibilities for the future of x-ray light sources. For instance, we expect that this x-ray source will be useful for studying ultrafast structural dynamics due to the predicted femtosecond temporal duration. In addition, medical imaging and treatment will be possible with further improvements in the average brightness. Finally, if higher-energy electron beams are used\[7\], the x-ray source can be used for photonuclear studies.
