Summary

A clinical trial was conducted to evaluate effects of two intervention strategies on the prevalence of E. coli O157:H7 shedding by feedlot steers using 384 steers and 48 pens. Intervention strategies were a direct fed microbial or vaccination against E. coli O157:H7. No differences in performance or carcass yield were observed for direct fed microbial or vaccination treatments, compared to the control. Vaccination significantly reduced the prevalence of E. coli O157:H7. In addition, we also observed a non-significant decrease in the prevalence of E. coli O157:H7 with inclusion of the direct fed microbial.

Introduction

Preliminary Nebraska research has indicated inclusion of direct fed microbials such as (Lactobacillus spp.) in the diet of beef animals, may reduce numbers of E. coli O157:H7 shed in the feces (Moxley, et al., 2000, unpublished observations; Brashears et al., 2003, Journal of Food Protection 66:748-754). Also, previous research indicated vaccination against E. coli O157:H7 type III secreted proteins reduced fecal shedding of this organism in experimentally inoculated cattle (6-month old calves and adult yearlings; Potter, et al., 2001 unpublished observations). Therefore, an experiment was conducted to evaluate effects of vaccination, and or inclusion of a direct fed microbial as intervention strategies on the prevalence and of E. coli O157:H7 being shed in the feces.

Procedure

Three hundred eighty-four medium framed steer calves (768 lb) were used in a feedlot finishing experiment. Steers were blocked into three weight groups and stratified by weight within block and assigned randomly into forty-eight pens (8 steers / pen). Pens within each block were assigned randomly to a 2 x 2 factorial treatment design; factors being with or without direct fed microbial (NPC 747) (Nutrition Physiology Corp.), or with or without vaccination treatment. Direct fed microbial product was mixed with water and applied to the feed truck mixing box and fed at a rate of 1x10⁹ colony forming units / steer / day. Steers were fed once daily with the control steers fed with a control feed truck and treatment steers fed with another treatment feed truck to minimize cross contamination. The finishing diet dry matter composition was 55% high moisture corn, 35% wet corn gluten feed, 5%corn silage, 2% alfalfa hay, 2% supplement, and 1% water (used to mix the direct fed microbial) (Table 1). Steer weights were taken for two consecutive days at the start of the experiment after a 3-day period of limit-feeding to equalize gut fill. Steers were fed for an average of 121 days. Steers were sampled one pre-treatment period and 5 experimental periods, resulting in one pre-treatment period and 5 experimental periods. Rectal fecal grab samples were obtained from each steer in each period. Vaccinations were given three times, beginning with the pre-treatment sampling and twice more during the first two experimental period samplings.

All fecal samples were taken immediately to the UNL E. coli lab and analyzed for presence of E. coli O157:H7 using procedures previously described (Smith, et al., 1999) with modifications. Ten-gram fecal samples were incubated 6 hr in Gram Negative (GN) broth containing vancomycin, cefixime and cefosulfodin. An aliquot of culture material was then subjected to immunomagnetic bead separation and plated onto sorbitol-MacConkey agar containing cefixime and tellurite (CT-SMAC). After an 18-24 hr incubation, three non-sorbitol-fermenting colonies were picked and subcultured onto CT-SMAC to ensure purity then were subcultured onto MacConkey and Fluorocult agars. After an 18-24 hr incubation, lactose-fermenting colonies that yielded a negative MUG (4-methylumbelliferyl-β-D-glucuronide) reaction were streaked with E. coli O157:H7 using procedures previously described (Smith, et al., 1999) with modifications. Ten-gram fecal samples were incubated 6 hr in Gram Negative (GN) broth containing vancomycin, cefixime and cefosulfodin. An aliquot of culture material was then subjected to immunomagnetic bead separation and plated onto sorbitol-MacConkey agar containing cefixime and tellurite (CT-SMAC). After an 18-24 hr incubation, three non-sorbitol-fermenting colonies were picked and subcultured onto CT-SMAC to ensure purity then were subcultured onto MacConkey and Fluorocult agars. After an 18-24 hr incubation, lactose-fermenting colonies that yielded a negative MUG (4-methylumbelliferyl-β-D-glucuronide) reaction were streaked for isolation on blood agar. After an overnight incubation, one colony per isolate on blood agar was tested for E. coli O157 and H7 antigens by latex agglutination. Isolates that

Calculation from 1996 NRC Model.
were positive for O157 antigen, regardless of H7 results, were tested in a 5-primer-pair multiplex polymerase chain reaction (PCR) assay that detected genes for E. coli O157, H7 Shigatoxins 1 and 2, and intimin. Detection of genes for O157, H7 and at least one other target in the assay was considered to be confirmation of an isolate as E. coli O157:H7.

Pen was considered the experimental unit, and the performance and proportion of culture-positive animals per pen during the period were the outcomes of interest. E. coli O157:H7 data were analyzed on a pen basis using repeated measures in the Mixed procedure of SAS assuming random block and compound symmetry. Performance data were statistically analyzed with the mixed procedures of SAS.

Results

E. coli Results

During the pre-treatment sampling period, the prevalence of E. coli O157:H7 was 31.0% (Table 2) and there were no significant (P=.19) differences among treatment groups. Average pen prevalence by treatment and period is summarized in Figure 1. During the experimental periods prevalence varied significantly over time (P=0.01), with period 1 having an overall prevalence of 18.5%. Period 2 declined in overall prevalence with 10.2%. Period 3 was static time (P=0.01), with period 1 having an overall prevalence of 11.7%.

Period 4 showed a slight, but not significant improvement of the direct fed microbial treatment with an average of 8.8% positive. The addition of a direct-fed microbial to the feed. A similar non-significant decrease in prevalence was observed in at least two recent experiments in other research facilities. This suggests the direct-fed microbial is effective in reducing prevalence. Therefore, because we saw no interaction we believe the two intervention strategies may be useful separately or in concert to reduce fecal shedding of E. coli O157:H7.

In conclusion, vaccination of steers with three injections of E. coli O157:H7 vaccine significantly reduced fecal shedding of E. coli O157:H7. We observed a non-significant trend to decrease the prevalence of E. coli O157:H7 in cattle feces, with the addition of a direct-fed microbial to the feed. A similar non-significant decrease in prevalence was observed in at least two recent experiments in other research facilities. This suggests the direct-fed microbial is effective in reducing prevalence. Therefore, because we saw no interaction we believe the two intervention strategies may be useful separately or in concert to reduce fecal shedding of E. coli O157:H7.
