ABSTRACT: Syncuaria mycteriae n. sp. (Nematoda: Acuarioidea) was collected under the lining of the gizzard of a wood stork, Mycteria americana L., from the Area de Conservacion Guanacaste, Costa Rica. The new species can be distinguished from all known species of Syncuaria by having irregular dotted ornamentations on the caudal alae of males, a complex distal end of the left spicule comprising 3 protuberances, and a spicule ratio of 1:9.3. Preliminary phylogenetic analysis of 11 Syncuaria spp. based on 9 morphological characters produced 2 equally parsimonious cladograms with a consistency index of 85%, differing only in the placement of S. hargilae. The phylogenetic analysis suggests that the new species is the sister species of S. leptoptili, whose male members have a single protuberance on the left spicule. Furthermore, the analysis suggests that the plesiomorphic host group for the genus is Ciconiiformes, specifically Ciconiidae (host for 5 species), with 2 species occurring in Threskiornithidae (also Ciconiiformes), possibly as a result of cospeciation, and 2 species each occurring in Pelecaniformes and Podicipediformes, resulting from 4 episodes of speciation by host switching.

Species of Syncuaria Gilbert, 1927, parasitize freshwater piscivorous birds belonging to the orders Ciconiformes, Pelecaniformes, and Podicipediformes, in which they are characteristically found under the gizzard lining (Wong et al., 1986). Gilbert (1927) described the first species of Syncuaria, S. ciconiae, inhabiting Ciconia ciconia L. and C. nigra L. in Georgia. Skrjabin et al. (1965) recorded 9 species of this genus. A revision of the genus Syncuaria was made by Wong et al. (1986), who regarded Skrjabinocara Kurashvili, 1940, Chordocephalus Alticranius, and Podicipediformes, in which they are characteris-

cically found under the gizzard lining (Wong et al., 1986). Since then, 1 additional species has been added to the genus (Digiani, 1999).

During June 1998, as part of an ongoing biodiversity inventory of the eukaryotic parasites of vertebrates inhabiting the Area de Conservacion Guanacaste (ACG) in northwestern Costa Rica (http://brooksweb.zoo.utoronto.ca/index.html), a new species of Syncuaria was collected from the wood stork, Mycterida americana L. This is the first report of Syncuaria from Mycteria or from Costa Rica.

MATERIALS AND METHODS

One wood stork, M. americana, was collected on 24 December 2001 and examined for parasites. Nematodes collected from beneath the lining of the gizzard were fixed in glacial acetic acid and preserved in 70% ethanol. They were later cleared in lactophenol for further examination. Drawings were made with a microscopy tube. Measurements were given in micrometers unless otherwise stated. Phylogenetic analyses were performed using standard Hennigian Argumentation (Brooks and McLennan, 2002); results were confirmed using the computer program PAUP 4.0b10*, implemented on a Macintosh G4 867 computer.

DESCRIPTION

Syncuaria mycteriae n. sp.
(Figs. 1–6)

Diagnosis: Medium sized nematodes. Lateral alae present, beginning at anterior part of the glandular esophagus, far from the cervical papillae, and extended posteriorly to the posterior part of body. Pseudolabia well developed, with conical apices, each bearing a pair of large cephalic papillae and 1 inconspicuous amphid. Cordons beginning at dorsal and ventral sides of oral opening, continuing posteriorly, anastomosing on lateral sides immediately anterior to small, bifid cervical papillae. Cordon narrow, consisting of wide-serrated, crescent-shaped cuticular plates. Cervical papilla 5.7–8.2% total body length (TBL) from anterior end. Esophagus clearly divided into short anterior muscular part and long posterior glandular part. Muscular esophagus, 4.1–5.7% TBL; glandular esophagus, 17.5–26.6% TBL. Nerve ring located at the level of the anterior end of the muscular esophagus. Excretory pore immediately posterior to nerve ring.

Male (n = 2): Body length 8.83 mm, 9.72 mm. Maximum width 259, 259. Cordons 629, 673 long. Lateral alae begin at anterior part of glandular esophagus, 600, 665 from the cervical papillae. Buccal capsule 222, 229 long. Muscular esophagus 475, 511 long and 52, 65 wide; glandular esophagus 2.26 mm, 2.59 mm long and 152, 170 wide. Nerve ring 274, 277 from anterior end, excretory pore 304, 311 from anterior end, and cervical papillae 665, 752 from anterior end. Posterior end of body curved. Caudal alae well developed, 455, 575 long, 5.2–5.9% TBL, with irregular dotted ornamentations. Four pairs of preanal and 5 pairs of postanal pedunculate papillae present. Sixth pair of postanal papillae sessile, smaller, internal to fifth pair. Spicules unequal and dissimilar. Left spicule 1.41 mm, 1.60 mm long, slender, with 3 protuberances on distal end (Fig. 5). Right spicule 152, 171 long, broad with simple distal end. Ratio of right spicule–left spicule 1:9.3.

Received 15 November 2002; revised 7 April 2003; accepted 7 April 2003.

FIGURES 1–6. Syncuaria mycteriae n. sp. 1. Anterior end of female, lateral view. 2. Posterior end of male, lateral view. 3. Caudal extremity of male, ventral view. 4. Posterior end of male, lateral view showing relative lengths of spicules. 5. Distal end of left spicule. 6. Posterior end of female, lateral view. Bars: 1, 4, 6 = 100 μm; 2, 3, 5 = 50 μm.
cuticular inflation, 346–361 (356) from posterior end, 2.5–2.8% (2.7%) TBL from posterior end. Ovijector consisting of 2 parts; vagina vera short, 174 long, thickly muscled; vagina uterina longer, 412 long, muscles weaker than that of vagina vera. Tail short, 65–106 (90) long, rounded, curved slightly dorsally. Eggs oval, thick shelled, embryonated, 26–28 (27) long, and 18–20 (19) wide.

**Taxonomic summary**

Type host: *Mycteria americana* L. (Aves: Ciconiiformes: Ciconiidae).

Type locality: Area de acampar, Sector Santa Rosa, ACG, Guanacaste Province, Costa Rica.

Site of infection: Under the lining of the gizzard.

Prevalence and intensity: Two males and 4 females in 1/1 host examined.

Type specimens: Holotype, USNPC 93541; allototype, USNPC 93542; paratype, USNPC 93543.

Etymology: The new species is named after its host genus.

**Remarks**

Wong et al. (1986) recently revised *Syncuaria* thoroughly. The new species can be readily distinguished from all known species of the genus by having irregular dotted ornamentations on the male caudal alae, by having a complex distal end of the left spicule comprising 3 protuberances, and by having a spicule ratio of 1:9.3 versus a range of 1:2.1–6.0 due primarily to having a longer left spicule than other species. The new species can be further distinguished from *S. ciconiae* Gilbert, 1927, *S. decorata* (Cram, 1927), *S. diacantha* Petter, 1961, *S. longialula* Wang, 1976, and *S. plegadisi* Digiani, 1999, by the presence of lateral alae.

Among the species having lateral alae, *S. mycteriae* can be distinguished from *S. bressoui* Gretillat, 1970, and *S. hargilae* (Baylis and Daubney, 1923) in having a longer left spicule (1,410–1,600 vs. 331–351 in *S. bressoui* and 595 in *S. hargilae*) and thus a different spicule ratio (1:9.3 vs. 1:3.9–4.5 in *S. bressoui* and 1:3.2 in *S. hargilae*). It further differs from *S. hargilae* in having the vulva 346–361 versus 100–102 from the posterior end. The new species differs from *S. buckleyi* (Ali, 1957) in having the vulva 346–361 versus 100–102 from the posterior end. The new species differs from *S. leptoptili* (Baylis and Daubney, 1923) and *S. squamata* (Linstow, 1883) by having narrow rather than well-developed caudal alae. Finally, the cephalic cordons in *Syncuaria* spp. are never recurrent, whereas they are reported as always recurrent in *Desportesius* and recurrent or not in *Skrjabinoclava*. We have summarized our above comparisons among species of *Syncuaria* phylogenetically on the basis of a suite of 9 characters listed below. Character states are taken from the revision by Wong et al. (1986) and the redescription of *S. decorata* by Baylis (1937) in addition to our specimens of *S. mycteriae*. Determination of plesiomorphic condition was based on out-group comparisons using primarily published reports of *Desportesius* and *Skrjabinoclava*:

3. Number of pairs of postanal papillae—0: 6, all papillose; 1: 5 papillose and 1 sessile; 2: 5 papillose and 2 sessile; 3: 5, all papillose; 4: 4, all papillose; 5: 3, all papillose.
4. Lateral alae—0: present; 1: lacking.
5. Cuticular ornamentation on caudal alae of male—0: lacking; 1: present.
7. Average spicule ratio—0: greater than 1:5 but less than 1:6; 1: greater than 1:4 but less than 1:5; 2: greater than 1:3 but less than 1:4; 3: <1:3; 4: 1:9.3.
8. Cordon width—0: narrow; 1: wide (condition found in *S. decorata* and *S. diacantha*; for comparisons, see figures in Wong et al., 1986).
9. Distal end of left spicule—0: simple; 1: 1 projection; 2: 3 projections.

Phylogenetic systematic analysis of these characters, all run unordered, produced 2 equally parsimonious cladograms (Fig. 7), each with a consistency index of 85% (a tree length of 23 steps for 23 apomorphic character states). The trees differ only with respect to their placement of *S. hargilae* based on whether lateral alae, once lost, can be regained evolutionarily (represented by the reversal to character state 4(0) in Fig. 7b). Some might consider characters 1, 2, and 7 to be different manifestations of the same trait, but the distribution of apomorphic traits on the trees suggests that they have evolved relatively independently. Finally, despite the very high consistency index in this preliminary analysis, basal relationships within the group are not well resolved, indicating that additional study of these species, as well as their putative sister groups, is needed.

**Discussion**

This report brings the number of species of *Syncuaria* currently recognized as valid to 11. Seven of these species inhabit Ciconiiformes, 2 inhabit Podicipediformes, and 2 inhabit Pelecaniformes. Five of the 7 species inhabiting Ciconiiformes are parasites of Ciconiidae (storks): *S. ciconiae* in *C. ciconia* L. from Georgia (Gilbert, 1927) and *C. nigra* L. from Georgia and Czechoslovakia (Macko, 1964); *S. bressoui* in *Leptoptilos cru-
menifer (Lesson) from Senegal (Gretillat, 1970); S. hargila in L. dabuis (Gmelin) from India (Baylis and Daubney, 1923); S. leptoptilos in L. crumenifer from Congo and Nigeria (Gendre, 1919) and Senegal (Gretillat, 1970) and in C. ciconia and C. nigra from Czechoslovakia (Macko, 1962); and S. mycteriae n. sp. in M. americana (wood stork) from Costa Rica (this report). The remaining 2 species inhabiting Ciconiiformes are parasites of Threskiornithidae (ibises and spoonbills): S. diacantha in captive specimens of Ajaja ajaja (=Platalea ajaja) from France (Petter, 1961) and in wild specimens of the same host from Cuba (Barus, 1966), the United States (Sepulveda et al., 1994), and Argentina (Digiani, 1999) and S. plegadisi in Plegadis chihi from Argentina (Digiani, 1999). The 2 species inhabiting Podicipediformes are parasites of Podicipedidae (grebes): S. decorata in Podiceps auritus (L.) from the United States (Cram, 1927), in Podiceps grisegena, Podiceps cristatus, and Podiceps nigrigollis from Kyrgyzstan, Russia, and Azerbaijan (Shigin, 1957; Iksanov and Tikch, 1965; Vaidova, 1965), in P. cristatus from Estonia (Jogis, 1963), in P. cristatus and P. griseigena from Kazakhstan (Gvozdev and Kasimzhanova, 1965), and in P. crassatus, P. nigrigollis, and Podiceps ruficollis from Czechoslovakia (Barus and Zajicek, 1967) and S. longialula in P. cristatus from China (Wang, 1976). Finally, the 2 species inhabiting Pelecaniformes are parasites of Phalacrocoracidae (cormorants): S. squamata in Phalacrocorax carbo from “Central Asia” (Linstow, 1883) and Azerbaidzhan, Armenia, Georgia, and Turkmenistan (Wong et al., 1986), in P. carbo and Phalacrocorax pygmaeus from Kazakhstan and Romania (Roman-Chiriac, 1965), in Phalacrocorax auritus floridanus from Cuba, and in P. a. auritus from Canada (Wong et al., 1986) and S. buckleyi (Ali, 1957) in Phalacrocorax niger (Fieilit) from India (Ali, 1957).

The cladogram (Fig. 7) supports an interpretation that Ciconiiformes and specifically Ciconiidae are the plesiomorphic host groups for Syncuaria spp. Threskiornithidae appears to be the plesiomorphic host for the S. diacantha–S. decorata–S. plegadisi clade. Ciconiids and threskiornithids are sister groups, so it is possible that the common ancestor of Syncuaria inhabited the common ancestor of the Ciconiidae + Threskiornithidae, but corroboration of this possible cospeciation event requires better
resolution of the basal relationships within Syncuaria. The 4 species inhabiting Podicipediformes and Pelecaniformes each appear to have arisen as a result of speciation after a host-switching event.

The specimens of *S. mycteriae* were collected from an ailing Wood Stork found nearly moribund in an open field. Like other members of the heron family, wood storks are commonly found around open areas of freshwater and marine water, where they can wade and search for small fish and crustaceans. The other hosts of *Syncuaria* spp. listed above have similar piscivorous habits, and all are associated strongly with aquatic environments. We expect to find additional examples of this parasite clade as we begin to collect more aquatic birds and seabirds living in the ACG.

**ACKNOWLEDGMENTS**

We are grateful to the scientific and technical staff of the ACG for supporting this study, in particular, Elda Araya, Roger Blanco, Carolina Cano, María Marta Chavarria, Felipe Chavarría, Roberto Espinoza, Dunia Garcia, Guillermo Jimenez, Elba Lopez, Sigifredo Marín, Alejandro Masis, Calixto Moraga, Fredy Quesada, and Petrona Rios. Thanks are also due to Dan Janzen and Winnie Hallwachs, scientific council of Canada to D.R.B. and by a grant from the MCZ Putnam Expedition Fund to D.C.
