NEW GENUS AND SPECIES OF APOROCOTYLIDAE (DIGENEA) FROM A BASAL ACTINOPTERYGIAN, THE AMERICAN PADDLEFISH, POLYODON SPATHULA, (ACIPENSERIFORMES: POLYODONTIDAE) FROM THE MISSISSIPPI DELTA

Stephen A. Bullard, Scott D. Snyder*, Kirsten Jensen†, and Robin M. Overstreet

Department of Coastal Sciences, University of Southern Mississippi, Gulf Coast Research Laboratory, 703 East Beach Drive, Ocean Springs, Mississippi 39564. e-mail: ash.bullard@usm.edu

ABSTRACT: Acipensericola petersoni n. gen., n. sp. (Digenea: Aporocotylidae) infects the heart of the American paddlefish Polyodon spathula (Walbaum, 1792) in the Mississippi Delta. It has robust, spike-like body spines arranged in ventrolateral transverse rows; a bowl-shaped anterior sucker centered on the mouth and having minute spines on the inner anteroventral surface only; a pharynx; an inverse U-shaped ceca extending to near the posterior body end, intercecal testes comprising a pre-ovarian testicular column plus a single testis posteriorly; an extensively lobed ovary located medially and immediately posterior to the testicular column; a spherical ootype that is intercecal and post-ovarian; a Laurer’s canal; and a common genital pore. The new species is the first-named aporocotylid collected from a basal actinopterygian. It resembles the chondrichthyian aporocotylids Chimaerohemecus trondheimensis, Orchistirius heterovitellatum, and Aggrandrotema cetorhini in having an inverse U-shaped ceca, but it is morphologically most similar to the anguilliform aporocotylid Pararcardicoloides yamaguti in having that feature plus a comparable anterior sucker, a single testis posteriorly, an intertesticular ovary, and a common genital pore. Sequence data for the complete small subunit ribosomal DNA (18S) do not refute its membership within Aporocotylidae nor its affinity to 1 of those aforementioned aporocotylids: A. petersoni was basal to the few teleost aporocotylids analyzed, and C. trondheimensis was the only taxon basal to A. petersoni. We regard the specimens of Spirorchis sp. previously reported from the shortnose sturgeon Acipenser brevoorstum Lesueur, 1818 as congeneric with the new species.

Adult blood flukes (Digenea: Schistosomatidea) infect jawed vertebrates (Gnathostomata) and historically have been grouped into 3 families correlating to the broad phylogenetic affiliations of their definitive host groups: Aporocotylidae Odhner, 1912 for those blood flukes that infect non-tetrapod gnathostomes, i.e., fishes (Smith, 1997a, 1997b, 2002); Spirorchidae Stunkard, 1921 for those of turtles (Platt, 2002); and Schistosomatidae Stiles and Hassall, 1898 for those of birds and mammals (Khalil, 2002). We concur with Stunkard (1921) who stated that, “In my opinion, the Aporocotylidae of fishes, the Spirorchidae of turtles, and the Schistosomatidae of birds and mammals constitute a well-defined group with inherent natural relationships.” At present, Aporocotylidae includes only 5 nominal species that infect cartilaginous fishes (Chondrichthy-es) (Bullard et al., 2006), plus >100 species that infect bony fishes (Actinopterygii: Teleostei) (see Smith, 1997a, 1997b). As such, aporocotylids infect definitive hosts allocated to widely separated gnathostome lineages, whereas all adult spirorchids and schistosomatids are reportedly restricted to members of Tetrapoda (Gnathostomata: Sarcopterygii). Although Aporocotylid ae is the most diverse blood fluke family, with respect to the number of named species and accepted genera, at least tens of aporocotylid species remain unnamed (S. Bullard, unpubl.), and many potential host lineages seem vastly under-explored for the presence of aporocotylid infections. Fewer than 200 (Smith, 1997b) of the nearly 28,000 valid fish species (Nelson, 2006) are reported as hosts, and most fish orders (46 of 63) reportedly lack infections. This void of information is a barrier to understanding the relationship between host ancestry and the evolution of fish blood flukes. Most notable among those under-ex- plored host lineages are the lower (basal) actinopterygyians (sen- nu Grande and Bemis, 1996), which form a non-monophyletic group of convenience that includes extant members allocated to 2 distinct lineages, i.e., Acpiperiformes (including paddle- fishes [Polyodontidae] and sturgeons [Acipenseridae]) and Poly- leriformes (including bichirs [Polypteridae] only) (e.g., Grande and Bemis, 1996; Nelson, 2006). Herein, we provide the first name and description for an aporocotylid that infects a basal actinopterygian, the American paddlefish Polyodon spathula (Walbaum, 1792) (Acipenseriformes: Polyodontidae) and propose a new genus to accommodate this new species.

MATERIALS AND METHODS

Adult blood flukes from the Mississippi Delta were captured with gill nets in April of 2004 and 2006. All fish were killed by spinal severance, and immediately afterwards the heart was extracted, placed in a sample bag, bisected to expose its lumen, immersed in an anticoagulant solution of ~5.0 gm NaCl and ~2.0 gm NaCl-citrate/L of distilled water, and kept in a cooler with a small amount of ice for several hours. Upon returning to the laboratory, the contents of the bag were examined with the aid of a dissecting microscope. Observations of liv- ing flukes were made with the aid of dissecting and compound microscopes. Flukes intended as whole mounts were killed with heat from an ethanol-burner flame, under little or no coverslip pressure, and transferred to a vial of 5% neutral buffered formalin (n.b.f.). Whole mounts were stained in Van Cleave’s hematoxylin with several additional drops of Ehrlich’s hematoxylin, made basic at 70% ethanol with lithium carbonate and butyl-amine, dehydrated, cleared in clove oil, and mounted in Canada balsam. Two specimens were embedded in paraffin, serially-sectioned at 4 µm, and stained with Gill’s hematoxylin and eosin. Three specimens for scanning electron microscopy (SEM) were dehydrated, immersed in hexamethyldisilazane for 30 min, air-dried for 45 min, and sputter-coated with gold-palladium. Drawings were made with the aid of a drawing tube and facilitated by differential interference contrast (DIC) optical components. Measurements are reported in µm and given as ranges with the sample size in parentheses. The specimen of “Spirorchis sp.” of Appy and Dadswell (1978) (USNPC No. 73138) was lost and presumably destroyed during Hurricane Katrina on 29 August 2005. Fish classification and higher level taxon names used herein follow primarily Grande and Bemis (1996) and Nelson (2006). Because “fishes” comprise a paraphyletic assemblage if one excludes Tetrapoda, we herein use that term not as a taxonomic rank but rather, as stated by Nelson (2006), “as a matter of convenience, essentially to describe
those vertebrates studied by ichthyologists and covered in ichthyological courses."

The specimens intended for molecular analyses were fixed directly in 95% EtOH, and genomic DNA was extracted using a DNeasy tissue kit (Qiagen, Valencia, California) according to the manufacturer’s instructions. Polymerase chain reaction (PCR) was used to amplify SSU rDNA with the forward primer 18SE (5′-CCG ACT TCG TCG ACA ACC TGG TTG ATC CTA CCA CTG) and the reverse primer WORMB (5′-CTT GTT AGC ACT TGT ATT TCC TCT) (Littlewood and Olson, 2001). Reactions were performed in a total volume of 25 μl and consisted of approximately 20 ng of gDNA, 0.2 μM of each primer, and 12.5 μl FidelTag PCR Master Mix (USB Corporation, Cleveland, Ohio). Reaction volume was brought to 25 μl with sterile deionized water. Amplification was performed on a Perkin Elmer GeneAmp 2400 thermocycler (Perkin Elmer, Waltham, Massachusetts) under the following conditions: 94°C for 4 min, followed by 40 cycles of 94°C for 30 sec, 50–56°C for 30 sec, and 72°C for 2 min, followed by 1 cycle of 72°C for 5 min. Unincorporated PCR primers and nucleotides were removed from PCR products using exonuclease I and shrimp alkaline phosphatase from a PCR Product Pre-Sequencing Kit (USB Corporation, Cleveland, Ohio). Sequences were determined directly from PCR templates using Big Dye terminator chemistry and an ABI Prism 3100 (Applied Biosystems, Forest City, California). Primers used in sequencing SSU rDNA sequenced the PCR primers and produced 138F (5′-AGG GTT CGA TTA CGG AG) and 1100F (5′-CAG AGT TTC GAA GAC GAT C) and the reverse primers CEST1R (5′-TTT GTG TTC GTC ACC TTC TCC CC) and 1270R (5′-CCG TCA TCC CCT TTA AGT) (Littlewood and Olson, 2001). Sequence data from the new species were aligned with sequences taken from GenBank. The ingroup consisted of the new species (GenBank DQ534192, Aporocotyle spinosicaniens (AY222177), Neoparacardicola nasonis (AY222097), Plethorchis acanthus (AY222096), and Chimaerohemecus trondheimiensis (AY157213). The sequence for Sanguinicola cf. inermis (AY22098) was included, although the identity of this species needs clarification because the DNA was extracted from a cercaria rather than from an adult specimen. Outgroups were selected from basal non-aporocotylid digeneans (senza Snyder, 2004) and included Alaria alata (AY222091) and Cardiophalloides longicolis (AY220809). Sequences were assembled using Contig Express (v. 8.0, InforMax, Invitrogen, Carlsbad, California) and provisionally aligned using Clustal W (Thompson et al., 1994), followed by alignment by eye in MacClade v. 4.06 (Sinaur and Associates, Sunderland, Massachusetts) (Maddison and Maddison, 2003). Positions for which alignment was ambiguous were removed before analysis. Maximum parsimony analysis of these data was performed using the "branch and bound search" algorithm of PAUP* (v. 4b10, Sinaur and Associates) (Swofford, 2001). Gaps were treated as missing data, and characters were unordered with equal weight. Nodal support was assessed using bootstrap resampling (Felsenstein, 1985) (1,000 bootstrap replicates, 100 heuristic searches/rePLICATE).

**DESCRIPTION**

*Acipecisericola* n. gen. (Figs. 1–28)

**Diagnosis:** Body flat, ventrally concave, elongate, <4 times longer than wide, with anterior and posterior ends tapering approximately equally, spined; tegumental body spines robust, spike-like, lacking recurved tip, in ventrolateral transverse rows. Roseothorn-shaped spines absent. Anterior sucker bowl-shaped, centered on mouth, spined; tegumental spines robust, spike-like, lacking recurved tip, arranged in distinct transverse rows (Fig. 2). "Branch and bound search" of "random sequence addition," and "TBR branch-swapping" options of PAUP* (v. 4b10, Sinaur and Associates) (Swofford, 2001). Gaps were treated as missing data, and characters were unordered with equal weight. Nodal support was assessed using bootstrap resampling (Felsenstein, 1985) (1,000 bootstrap replicates, 100 heuristic searches/rePLICATE).

**Acipecisericola petersoni** n. sp. (as *Spirorchis* sp. of Appy and Dadswell [1978]).

**Remarks**

The new genus resembles the monotypic genera *Chimaerohemecus* (van der Land, 1967), *Orchispirium* Madhavi and Rao, 1970, *Hyperorotrrema* Maillard and Ktari, 1978, and *Paracardicola* Martin, 1974, in having inverse U-shaped cecum. It also has affinities to both *Chimaerohemecus* and *Hyperorotrrema* by having a Laurer’s canal, not present, or at least not reported, in any other aporocotylid genera. *Acipecisericola*, however, is most similar to *Paracardicola* because it has a comparable anterior sucker (oral disc of Martin [1974]), a separate testis posteriorly, an intertesticular ovary, and a common genital pore. It is noteworthy that the ventrolateral nerve cords of both *A. petersoni* and *Paracardicola* are all ovoviviparous, i.e., they are blind-ending in the anterior end of the body posterior to the level of the mouth. *Acipecisericola* is easily differentiated from these and all other aporocotylid genera in having a large, bowl-shaped anterior sucker with minute spines on the inner anterolateral surface only (Figs. 1, 7, 12, 19) and an obvious, highly muscular pharynx (Figs. 1, 7, 12). In addition to that combination of features, the shape and orientation of the ventrolateral body spines differentiates the new genus. It has ventrolateral body spines that are spike-like and arranged in distinct transverse rows (Fig. 2). *Chimaerohemecus* and *Hyperorotrrema* each have 1 or 2 ventrolateral columns of C-shaped body spines (Van der Land, 1967; Maillard and Ktari, 1978; Bullard et al., 2006), *Paracardicola* has straight body spines that are distributed in a narrow ventrolateral field (Martin, 1974; Nolan and Cribb, 2004), and *Orchispirium* lacks spines altogether (Maddhavi and Rao, 1970). None of the remaining accepted genera of Aporocotylidae, all of which comprise species that infect bony fishes (Teleostei) only, have a bowl-shaped anterior sucker, strongly muscular pharynx, inverse U-shaped ceca, or Laurer’s canal.
FIGURES 1–4. *Acipensericola petersoni* from the heart of *Polyodon spathula*, ventral view. (1) Body of holotype showing anterior sucker (as), pharynx (ph), nerve commissure (nc), esophagus (es), cecal bifurcation (cb), testes 1–6 (t1–t6), ovary (o), and excretory pore (ep). Bar = 500 μm. (2) Transverse rows of ventrolateral body spines, paratype. Bar = 50 μm. (3) Juvenile, body showing anterior sucker (as), pharynx (ph), esophagus (es), and intestinal anlagen (ia). Bar = 200 μm. (4) Genitalia, composite, ventral view, showing posterior-most testis of testicular column (t5), uterus (u), uterine eggs (ue), anterior trunk of vasa efferentia (ave), vas deferens (vd), ovary (o), everted cirrus (ec), seminal vesicle (sv), primary vitelline collecting duct (vt), Laurer’s canal (lc), ootype (oo), posterior trunk of vasa efferentia (pve), oviduct (ov) with sperm and serving as oviducal seminal receptacle, and posterior-most testis (t6). Bar = 200 μm.

prepared specimens): Body 2,405–4,026 (10) long, 810–1,325 (10) wide, 2.9–3.2 times longer than wide (Fig. 1); dorsum with honeycomb-like surface features (Figs. 21, 22, 28); ventral surface relatively smooth medially (Fig. 18). Body spines 7–12 (8) long (Figs. 2, 11), nearly indistinct in some whole mounted specimens; proximal end broadly rounded (Fig. 2); distal end with sharp tip protruding only slightly from tegument (Fig. 24). Spine rows 10–12 (7) long, numbering 110–135 (3) per side, indistinct in posterior region of some specimens, not contiguous posteriorly. Ventrolateral nerve cord becoming confluent with paired cord 75–233 (5) or 4–6% of body length from posterior body.
Figures 5–6. Acipensericola petersoni from the heart of Polyodon spathula, ventral view. (5) Posterior body end of paratype showing posteriormost testis (t6), mononucleate cells (mc) of cecal wall, distal end of dextral cecum (c), nerve cord (nc), excretory vesicle (ev), and dorsal, subterminal excretory pore (ep). Bar = 200 μm. (6) Paratype showing junction of Laurer’s canal (Lc), vitelline duct (vt), and oviduct (ov). Ootype (oo), glandular ducts (gd), and proximal portion of uterus (ut). Bar = 100 μm.

Figures 7–10. Acipensericola petersoni from the heart of Polyodon spathula, adult, longitudinal sections. (7) Anterior region showing anterior sucker (as) and pharynx (ph). Dorsal (d) and ventral (v) surfaces. Bar = 50 μm. (8) Blackish residue, probably partially-digested blood components, occupying the cecal lumen (cl). Bar = 50 μm. (9) Posterior end showing excretory vesicle (ev) and subterminal excretory pore (ep) opening on dorsal surface. Bar = 50 μm. (10) Terminal genitalia showing common genital pore (arrow), cirrus (c), and cirrus sac (cs). Bar = 25 μm.
Body 663 long, 98 wide; ventrolateral body spines indistinct.

**Polyodon spathula**

**Acipenserericola petersoni** from the heart of 

![Image 115x453 to 581x751](image)

**Figures** 11–17. *Acipenserericola petersoni* from the heart of *Polyodon spathula*, ventral view, light micrographs. (11) Anterior ventrolateral surface showing sensory papillae (sp) and several transverse rows (r) of ventrolateral body spines, paratype. Bar = 30 μm. (12) Anterior sucker (as) and pharynx (ph) of paratype. Bar = 60 μm. (13) Posterior esophageal swelling (es) immediately anterior to cecal bifurcation (c), paratype. Bar = 30 μm. (14) Distal end of dextral cecum showing large, basophilic mononucleate cells (mc) of cecal wall. Bar = 60 μm. (15) Egg ejected from uterus, paratype. Note the thin egg shell that lacks an operculum. Bar = 20 μm. (16) Posterior end of paratype showing Y-shaped terminal excretory features immediately posterior to posterior testis (t); excretory vesicle (ev) and pore (ep) plus dextral (dd) and sinistral (sd) collecting ducts. Bar = 35 μm. (17) Ootype (oo) and surrounding glandular ducts of Mehlis’ gland (mg) adjacent to proximal region of seminal vesicle (sv), paratype. Bar = 25 μm.

**Diagnosis of juvenile** (based on 1 whole mounted specimen from heart): Body 663 long, 98 wide; ventrolateral body spines indistinct. Nervous system indistinct. Sensory papillae not evident. Anterior sucker 35 in diameter. Pharynx 60 long, 40 wide. Esophagus 102 long or 15% of body length, 8 wide immediately posterior to pharynx, extending directly posterior; posterior esophageal swelling 28 long, 12 wide.
**Figures 18–28.** *Acipensericola petersoni* from the heart of *Polyodon spathula*, adult specimens, scanning electron micrographs. (18) Body, ventral view. Bar = 100 μm. (19) Ventral aspect of anterior sucker, lateral view. Bar = 10 μm. (20) Sensory papillae (circled) on ventral surface of body. Bar = 5 μm. (21) Body, dorsal view. Anterior sucker (as). Bar = 100 μm. (22) Anterior sucker (as), dorsal view. Bar = 100 μm. (23) Ventrolateral surface of body showing dispersion of sensory papillae (sp). Bar = 10 μm. (24) Spine row showing protruding tips of ventrolateral body spines (s). Bar = 0.5 μm. (25) Anterior sucker (as) and mouth (m), ventral view. Bar = 10 μm. (26) Higher magnification of Figure 25 showing anterior sucker spines (s). Bar = 4 μm. (27) Higher magnification of Figure 26 showing cluster of spines on the inner anteroventral surface of the anterior sucker. Bar = 2 μm. (28) Tegument of body, dorsal view. Bar = 10 μm.

Esophageal gland indistinct. Cecal anlagen appearing as a sac-like medially-positioned mass (Fig. 3). Terminal genitalia, gonads, and excretory system not evident.

**Taxonomic summary**

*Type and only known host:* *Polyodon spathula* (Walbaum, 1792) (*Acipenseriformes*: Polyodontidae), the American paddlefish.

*Sites:* Adults and juvenile in atrium, ventricle, and bulbous arteriosus of heart.

*Type locality:* Six Mile Lake (33°41’14”N, 90°12’39”W), an oxbow of the Tallahatchie River near Greenwood, Mississippi. Other locality: Lower Lake (34°24’26”N, 89°43’12”W), a tailrace comprising the upper portion of the Little Tallahatchie River exiting Sardis Lake Reservoir, near Batesville, Mississippi.

*Specimens deposited:* Holotype USNPC No. 100676. Paratypes USNPC Nos. 100677–100678.

*Prevalence of infection:* Nine of 11 (82%) from Six Mile Lake and 6 of 6 (100%) from Lower Lake.

*Etymology:* The specific name ‘*petersoni*’ honors Jody Lee Peterson (Parasitology Section, Gulf Coast Research Laboratory) for his intuition and skill as a fisherman and for his invaluable field assistance to SAB during 1997 through 2007.

*Remarks*

Live specimens of *Acipensericola petersoni* used their flat, ventrally-concave surface and their ventrolateral body spines for attachment and locomotion. Like some other crawling aporocotylids that have been observed (Bullard and Overstreet, 2002, 2003, 2004), these flukes adhere to the walls of the heart, as well as to glass and plastic surfaces, by using the lateral body margin, presumably as a gasket that creates and maintains an internal negative pressure between the fluke’s body and the attachment surface. Specimens crawled by repeated, wave-like un-
dulations of the lateral body margins. As with adults of some species of *Cardiocola*, as well as with *Elaphobrutes excent* Bullard and Overstreet, 2003, the transverse rows of ventral lateral body spines of *A. petersoni* probably enhance grip and traction for attaching to, and crawling over, uneven fleshy surfaces. However, these spines apparently are not required for initial attachment and crawling since adults adhered to, and crawled over, impervious surfaces, e.g., glass and plastic, and the juvenile specimen lacked spines altogether (Fig. 3). Regarding the function of the anterior sucker, a few live specimens applied their anterior sucker to the surface of the plastic sample bag and remained anchored there, even after the bag was shaken vigorously. These specimens, however, could be dislodged by inserting the bristles of an artist’s brush beneath the rim of the anterior sucker.

Parsimony analysis of SSU data (Fig. 29) derived from a single specimen of *A. petersoni*, as well as from several other aporocotylids, produced a single most-parsimonious tree with nodal support ranging from 74–100 and a tree length of 1,311 (224 of the 1,815 total base pairs sequenced were informative). The tree topology showed that *C. trondheimensis*, a chondrichthyan blood fluke, was the most basal ingroup taxon in the tree, with *A. petersoni* basal to *Sanguinicola cf. inermis*, both of which were basal to 3 euteleost (Euteleostei) aporocotylids included in the analysis, i.e., *Aporocotyle spinosicanalis*, *Plethorchis acanthus*, and *Neoparacardicola nasonis*.

**DISCUSSION**

At least 1 species of the new genus infects a sturgeon in North America. This reported (Appy and Dadswell, 1978), previously collected, but unnamed aporocotylid infects the mesenteric vessels of shortnose sturgeon (*Acipenser brevirostrum* LeSueur, 1818 [Acipenseridae]) in the Saint John River Estuary, New Brunswick, Canada. Appy and Dadswell (1978) detailed 9 immature specimens and identified the specimens as *Spirorchis* sp.; however, we regard the unnamed species as congeneric with *A. petersoni* because it has: (1) a prominent, bowl-shaped anterior sucker that is centered on the mouth; (2) a clearly delineated pharynx that is located immediately posterior to the anterior sucker; (3) an inverse U-shaped ceca that extends to near the posterior body end; (4) a testicular column; and (5) ventrolateral body spines. Although ventrolateral body spines were neither described nor illustrated by Appy and Dadswell (1978), we examined a voucher specimen (USNPC No. 73138) and confirmed the presence of ventrolateral spines. However, since we could not discern ventrolateral body spines in the juvenile specimen of *A. petersoni* in our collection (Fig. 3), perhaps some of the younger specimens collected by Appy and Dadswell also lacked them. In addition, ventrolateral body spines can be overlooked quite easily because of their small size and, in poorly fixed specimens, these spines may be lost because the thin margins of the body seem to be especially vulnerable to autolysis, which can result in the subsequent detachment of the spines. The specimens of Appy and Dadswell (1978) from the sturgeon remain unidentified, and not yet ready to be described, because no adult aporocotylid material from a shortnose sturgeon has been reported or examined by us. We suspect that it represents a species distinct from *A. petersoni*. As previously stated, the morphological features of the species certainly indicate that it belongs in *Acipensericolca*, but its host’s phylogenetic affiliation (Acipenseridae rather than Polyodontidae) and geographic distribution (New Brunswick River draining to northwestern Atlantic Ocean rather than the Mississippi River drainage) suggest that it represents a new species. Addressing this taxonomic problem should require detailed necropsies of freshly killed, wild-caught shortnose sturgeons. Unfortunately, such an opportunity is rare and has proven logistically difficult for us to arrange because the shortnose sturgeon, like nearly all sturgeon species, is presently protected throughout its range.

Collectively, aporocotylids exhibit several different morphological types of suckers associated with the mouth (Bullard and Overstreet, 2003), and we think that the fine features associated with these various types of suckers help elucidate evolutionary relationships within the group. Hereinafter, we refer to them as...
“anterior suckers.” The shape of the sucker, the spines of the sucker, and the location of the mouth are diagnostic for at least some genera, e.g., Elaphrophates Bullard and Overstreet, 2003. Homology of these various anterior suckers presently is uncertain for some taxa, which represents a barrier to understanding the phylogenetic interrelationships among aporocotylid genera. Demonstrating homology of these various suckers is beyond the scope of the present paper because it requires a complete phylogenetic analysis of the family; however, we regard the anterior suckers of A. petersoni and P. yamaguti as 2 slightly different variations of the same homologous sucker type, and we herein delineate that type from those of other aporocotylids by its general shape and the relative position of the mouth. In Acipensericoa and Paracardicoidea, unlike all other accepted aporocotylid genera, the anterior sucker is bowl-like, centered on the mouth, and demarcated from the anterior body end by a short trunk or peduncle that supports the sucker and can direct it anteroventrally (Figs. 1, 25; Fig. 3 of Martin [1974]). Despite these general similarities, the pharynx and spination associated with the anterior sucker differs among the species of Acipensericoa and Paracardicoidea. The anterior sucker of A. petersoni has spines on its inner anterovelar surface only and is accompanied by a muscular pharynx, whereas that of P. yamaguti reportedly lacks exposed spines and an associated pharynx. The bowl-shaped anterior sucker of Acipensericoa and Paracardicoidea is superficially like that of a spirorchiid because it is relatively large and centered on the mouth, but these aporocotylid genera have a peduncle associated with the sucker. In contrast, the spirorchiids studied by 1 of us (S.A.B.) have a sucker that is more strongly muscular and wholly invested in the forebody; there is no obvious peduncle or demarcation between the sucker and body-proper that can be discerned from fixed, stained whole mounts. Based on this feature, we suspect that the anterior sucker (“oral sucker”) of spirorchiids (Platt, 2002) is not readily comparable to that of Acipensericoa and Paracardicoidea.

Our understanding of the phylogenetic interrelationships of aporocotylids remains unclear because no clade-based phylogenetic hypothesis involving morphological or molecular sequence data for the majority of aporocotylid genera has been published. Two obvious obstacles to completing such a task are (1) several of the most specious aporocotylid genera need revision, e.g., Aporocotyle Odhner, 1900, Cardicola Short, 1953, and Sanguinicolia Plehn, 1905, and (2) type material for many of the named species in those genera are in poor condition or not available to borrow. Although a taxonomic revision and phylogenetic analysis of Aporocotylidae are in preparation by 1 of us (S.A.B.), additional descriptions of new aporocotylid species that infect fishes belonging to previously undocumented host lineages promise to further advance our knowledge of how these fishes evolved among various lineages of “fish.” The results of the present study offer some preliminary insight into the potential interrelationships among particular aporocotylid genera and their host groups and provide a framework from which to test future hypotheses about aporocotylid-fish co-phylogeny. For example, the morphological similarities we observed between A. petersoni and those aporocotylids that infect non-euteleost fishes indicate a strong phylogenetic affiliation among these genera. Further, the available SSU data indicate that non-euteleost aporocotylids are basal to those that infect euteleosts (Fig. 29). This preliminary result contradicts the notion that fish blood flukes lack a detectable level of phylogenetic host specificity to their definitive hosts.

ACKNOWLEDGMENTS

We thank Thomas Platt (St. Mary’s College, Notre Dame, Indiana) for graciously providing the specimens representing species of Spirorchis MacCallum, 1919, Carettacola Manter and Larson, 1950, Leucodiastoma Price, 1934, Hapalotrema Looss, 1899, Monticellias Mehra, 1939, Amphiorchis Price, 1934, and Vasotrema Stunkard, 1928, that helped us gain an appreciation for the oral sucker(s) of spirorchiids. We thank Jody Peterson of the Gulf Coast Research Laboratory (GCRL) for helping collect aporocotylids from paddlefishes in the Mississippi Delta, Ricky Campbell (United States Fish and Wildlife Service, Private John Allen National Fish Hatchery) and Dan O’Keefe (Mississippi State University, College of Forest Resources) for helping locate and capture paddlefishes; Eric Hoberg and Pat Plitt (United States National Parasite Collection) for providing voucher specimens; and Catherine Schloss, Joyce Shaw, and Margorie Williams (all Gunter Library, GCRL) for providing library assistance, National Science Foundation Grants 0508856, 0529684, and 0608603 supported this work.
