Estimating Percent Residue Cover Using the Line-Transect Method

This NebGuide describes how to use the line-transect method to estimate the percentage of the soil surface covered with crop residue.

David P. Shelton, Extension Agricultural Engineer
Roger Kanable, Conservation Agronomist, Soil Conservation Service
Paul J. Jasa, Extension Engineer--Conservation Tillage

- Find a representative area
- Stretch tape or line diagonally across crop rows
- Check for residue at each mark
- Determine percent cover
- Take at least three measurements
- Conclusion

Crop residue left on the soil surface is one of the easiest and most cost-effective methods of reducing soil erosion. Research in Nebraska and other midwestern states has shown that leaving as little as 20 percent of the soil surface covered with crop residues can reduce soil erosion by one-half of what it would be from residue-free conditions. Greater amounts of residue cover will further reduce erosion. (Refer to NebGuide G81-544, Residue Management for Soil Erosion Control, for further details on the erosion process and the benefits of residue cover.)

Many Conservation Plans specify crop residue management or residue left on the soil surface as the primary erosion control method. Generally, the amount of cover required after planting ranges from 20 percent to as much as 85 percent.

It is important to accurately determine percent residue cover to verify compliance and effective erosion control. Residue cover cannot be estimated merely by looking across a field. Such estimates, often made from the road or edge of the field, grossly overestimate the actual amount of cover. Accurate estimates of residue cover can only be obtained from measurements taken within the field, while looking straight down at the soil and residue.

The line-transect method is one of the easiest and most accurate methods of estimating percent residue cover. A 100 foot measuring tape is used most often, but other tape lengths, specially made cords with
"beads" attached, or knotted ropes will also work, (Figure 1). For convenience, there should be 100 easily visible marks on the measuring device.

![Figure 1. Measuring devices used for determining percent residue cover: tape measures; specially made cord with attached plastic beads; and knotted rope. For convenience, there should be 100 clearly visible marks on the measuring device.](image)

To use the line-transect method, the measuring device is first stretched across a section of the field. Percent residue cover is then obtained by counting the number of marks on the measuring device that are directly over a piece of residue. Following is a step-by-step procedure:

**Find a representative area:**

Select an area that is representative of the whole field. Avoid end rows, or small areas of the field that have been adversely affected by flooding, drought, weed or insect infestations, compaction or other factors that have substantially reduced yields or affected residue cover.

**Stretch tape or line diagonally across crop rows:**

Anchor one end of the tape or line and stretch it diagonally at about a 45 degree angle across the crop rows so it crosses more than one pass of the implements used. This avoids inaccurate readings such as those obtained if all measurements were taken in a windrow of residue left by the combine, or in an area of reduced amounts of residue. Do not take measurements parallel or perpendicular to crop rows.

**Check for residue at each mark:**

Measure residue cover by counting the number of marks that are directly over a piece of residue. (An inexpensive click or lap counter, available at sporting goods stores, can be useful to help keep count.)

When looking at the tape and counting, follow these rules:

1. Keep both ends of the tape anchored and do not move the tape.
2. Look straight down at the tape and marks.
   - Leaning from side to side will result in overestimation because residue may appear to be under the mark when it really is not.
   - To get an accurate measurement, count only those marks that have residue exactly under them (Figure 2).
3. Consistently look at the same side of the tape.
4. Consistently look at the same point at each mark.
   - This is especially important when using a knotted rope or cord with attached beads. The knot or bead covers a relatively large area, and if residue at any location under the mark is counted, overestimation will result. Instead, always focus on a small, single point such as where the bead meets the cord (Figure 3).
5. Do not count if questionable.

![Figure 2](above). While consistently looking at only one side of the measuring device, count only those marks that have a piece of residue beneath them.

![Figure 3](above). At each mark, consistently focus on a single point on the same side of the measuring device, rather than on the entire mark.
To effectively reduce erosion, a piece of residue needs to be large enough to dissipate the energy of a raindrop during an intense storm. Consider a dot of 3/32 inch in diameter as the minimum size suggested for residue to be counted. Use your judgment, but if you are not sure whether the piece of residue is large enough to absorb the raindrop energy, do not count it.

One way to determine if a piece of residue is large enough to count is to use a 3/32 inch diameter brazing rod, wooden dowel, or the unsharpened lead from a wooden pencil. The end of the rod is used to touch the residue at each mark. If the piece of residue extends completely beyond all edges of the rod, count it. If the rod completely covers the piece of residue, or if part of the rod end extends beyond the edge of the residue at any location, the point shouldn't be counted, because a raindrop falling on this location would strike some bare soil (Figure 4).

Figure 4. Measuring tape and 3/32 inch diameter rod being used to determine whether or not to count a piece of residue.

Determine percent cover:

When 100 points are observed, the number of marks that are directly over residue will be a direct measurement of the percent cover for that area of the field. That is, if 35 marks on a 100 foot tape were observed to be exactly over a piece of residue, then the residue cover is 35 percent.

If less than 100 points are observed, multiply the count by the appropriate conversion factor to obtain percent cover. For example, if a 50 foot tape is used, and only the foot marks are observed, multiply the count by two.

Take at least three measurements:

For increased accuracy, repeat the measuring process in three or more representative areas of the field. Average the individual measurements to obtain an estimate of percent cover for the entire field.

Conclusion

Crop residue management, or leaving residue on the soil surface, is the most cost-effective method of reducing soil erosion available to Nebraska farmers. Accurate measurements of percent residue cover are needed to determine if enough cover is present to adequately reduce erosion and to comply with the conservation provisions of the 1985 Food Security Act and the 1990 Food, Agriculture, Conservation, and Trade Act (Farm Bills). The line-transect method is one of the easiest and most accurate methods of determining percent residue cover. It is also the most reliable way to determine if the residue levels
specified in your Conservation Plan are being met.
