**Abstract:** Aeolian deposits in the North American Great Plains are important sources of Holocene palaeo-Abstract: Aeolian deposits in the North American Great Plains are important sources of Holocene palaeo-<br>environmental records. Although there are extensive studies on loess and dune records in the region, little is Abstract: Aeolian deposits in the North American Great Plains are important sources of Holocene palaeo-<br>environmental records. Although there are extensive studies on loess and dune records in the region, little is<br>known a known about records in aeolian cliff-top deposits. These are common on table (mesa) edges in the White River Badlands. These sediments typically have loam and sandy-loam textures with dominantly very fine sand, known about records in aeolian cliff-top deposits. These are common on table (mesa) edges in the White River<br>Badlands. These sediments typically have loam and sandy-loam textures with dominantly very fine sand,<br>0.5–1% org Badlands. These sediments typically have loam and sandy-loam textures with dominantly very fine sand,  $0.5-1\%$  organic carbon and  $0.5-5\%$  CaCO<sub>3</sub>. Some of these aeolian deposits are atypically coarse and contain granul 0.5–1% organic carbon and  $0.5-5\%$  CaCO<sub>3</sub>. Some of these aeolian deposits are atypically coarse and contain granules and fine pebbles. Buried soils within these deposits are weakly developed with A-C and A-AC-C profiles granules and fine pebbles. Buried soils within these deposits are weakly developed with A-C and A-AC-C<br>profiles. Beneath these are buried soils with varying degrees of pedogenic development formed in fluvial,<br>aeolian or co aeolian or colluvial deposits. Thickness and number of buried soils vary. However, late-Holocene soils from several localities have ages of approximately 1300, 2500 and 3700 <sup>14</sup>C yrs BP. The 1300 <sup>14</sup>C yr BP soil is cumu several localities have ages of approximately 1300, 2500 and 3700  $^{14}$ C yrs BP. The 1300  $^{14}$ C yr BP soil is several localities have ages of approximately 1300, 2500 and 3700 <sup>14</sup>C yrs BP. The 1300 <sup>14</sup>C yr BP soil is cumulic, with a thicker and lighter A horizon. Soils beneath the cliff-top deposits are early-Holocene (typically cumulic, with a thicker and lighter A horizon. Soils beneath the cliff-top deposits are early-Holocene (typically 7900 but as old as 10000<sup>-14</sup>C yrs BP) at higher elevation (~950 m) tables, and late-Holocene (2900<sup>-14</sup>C y BP) at lower ( $\sim$ 830 m) tables. These age estimates are based on total organic matter  $^{14}C$  ages from the top 5 cm of buried soils, and agreement is good between an infrared stimulated luminescence age and bracketing BP) at lower (~830 m) tables. These age estimates are based on total organic matter <sup>14</sup>C ages from the top 5 cm of buried soils, and agreement is good between an infrared stimulated luminescence age and bracketing <sup>14</sup>C 5 cm of buried soils, and agreement is good between an infrared stimulated lum<br><sup>14</sup>C ages. Our studies show that cliff-top aeolian deposits have a history similar to<br>on the Great Plains, and they are another source of pala on the Great Plains, and they are another source of palaeoenvironmental data.<br>**Key words:** Aeolian, buried soil, cliff-top deposits, South Dakota, badlands, mesa, Great Plains, Holocene.

#### Introduction

**Introduction**<br>Late-Quaternary aeolian deposits cover much of the semi-arid<br>Nath American Gract Plains (There and Smith, 1953; Ecroca Late-Quaternary aeolian deposits cover much of the semi-arid<br>North American Great Plains (Thorp and Smith, 1952; Forman Late-Quaternary aeolian deposits cover much of the semi-arid<br>North American Great Plains (Thorp and Smith, 1952; Forman<br>*et al.*, 2001; Muhs and Zárate, 2001). ACT deposits are narrow mantles of sediment that thin<br>residue that thin of a variety of Quaternary aeolian deposits in the White River<br>Badlands. ACT deposits are narrow mantles of sediment that thin<br>rapidly away from escarpment crests (Sharp, 1949; Wilson, 1989;

Pye and Tsoar, 1990; Hetu, 1992; Begin *et al*., 1995; David, Pye and Tsoar, 1990; Hetu, 1992; Begin et al., 1995; David, 1995). Unvegetated escarpment faces typically serve as a local 1995). Unvegetated escarpment faces typically serve as a local sediment source for ACT deposits (Wilson, 1989; Hetu, 1992; 1995). Unvegetated escarpment faces typically serve as a local sediment source for ACT deposits (Wilson, 1989; Hetu, 1992; Begin *et al.*, 1995; David, 1995), and processes contributing to sediment source for ACT deposits (Wilson, 1989; Hetu, 1992; Begin *et al.*, 1995; David, 1995), and processes contributing to the formation of ACT deposits are well documented. According the mind tunity of the mind tunity Begin *et al.*, 1995; David, 1995), and processes contributing to the formation of ACT deposits are well documented. According to wind-tunnel investigations by Bowen and Lindsey (1977), as the formation of ACT deposits are well documented. According<br>to wind-tunnel investigations by Bowen and Lindsey (1977), as<br>air passes over an escarpment its velocity increases and may be to wind-tunnel investigations by Bowen and Lindsey (1977), as<br>air passes over an escarpment its velocity increases and may be<br>almost twice the original velocity at the crest. Flow separation<br>these these immediately develop air passes over an escarpment its velocity increases and may be almost twice the original velocity at the crest. Flow separation takes place immediately beyond the crest and any sediments entrained during the acceleration almost twice the original velocity at the crest. Flow separation takes place immediately beyond the crest and any sediments<br>entrained during the acceleration are deposited. Based on research<br>in southwestern Saskatchewan, David (1995) suggested that ACT entrained during the acceleration are deposited. Based on research<br>in southwestern Saskatchewan, David (1995) suggested that ACT<br>sediment is derived from colluvium that forms on the slopes durin southwestern Saskatchewan, David (1995) suggested that ACT<br>sediment is derived from colluvium that forms on the slopes dur-<br>ing dry periods. Soils form in the ACT deposits during moister sediment is derived from colluvium that forms on the slopes during dry periods. Soils form in the ACT deposits during moister periods when spring rains wash the source sediment completely ing dry periods. Soils form in the ACT deposits during moister periods when spring rains wash the source sediment completely downslope. Hetu (1992) further suggested that these processes are periods when spring rains wash the source sediment completely<br>downslope. Hetu (1992) further suggested that these processes are<br>a significant component of bluff erosion, that infrequent highdownslope. Hetu (1992) further suggested that these processes are<br>a significant component of bluff erosion, that infrequent high-<br>magnitude storms may entrain 165 g material, and that the poor a significant component of bluff erosion, that infrequent high-<br>magnitude storms may entrain 165 g material, and that the poor<br>sorting typical of ACT deposits results from variable wind-gust magnitude storms may entrain 165 g material, and that the p sorting typical of ACT deposits results from variable wind-gone speeds and the deposition of sediments on snow (nivation). sorting typical of ACT deposits results from variable wind-gust<br>speeds and the deposition of sediments on snow (nivation).<br>Previous studies have noted the presence of ACT deposits in

speeds and the deposition of sediments on snow (nivation).<br>
Previous studies have noted the presence of ACT deposits in<br>
the White River Badlands of South Dakota (White, 1960;<br>
Herberg 1967; Herberg and Marchardd, 1960; He Previous studies have noted the presence of ACT deposits in<br>the White River Badlands of South Dakota (White, 1960;<br>Harksen, 1967; 1968; Harksen and Macdonald, 1969). Harksen the White River Badlands of South Dakota (White, 1960; Harksen, 1967; 1968; Harksen and Macdonald, 1969). Harksen (1967) was among the first to conduct detailed studies of aeolian Harksen, 1967; 1968; Harksen and Macdonald, 1969). Harksen<br>(1967) was among the first to conduct detailed studies of aeolian<br>deposits on upland surfaces in the badlands. Although his interest (1967) was among the first to conduct detailed studies of aeolian deposits on upland surfaces in the badlands. Although his interest was drawn primarily to older aeolian deposits, which he formally deposits on upland surfaces in the badlands. Although his interest<br>was drawn primarily to older aeolian deposits, which he formally<br>named the Red Dog Loess (Harksen, 1968), he did document the was drawn primarily to older aeolian deposits, which he formally<br>named the Red Dog Loess (Harksen, 1968), he did document the<br>presence of younger aeolian deposits, including ACT deposits.<br>Herberg (1970) and Prince (1974) named the Red Dog Loess (Harksen, 1968), he did document the presence of younger aeolian deposits, including ACT deposits.<br>Harksen (1968) and Briggs (1974) suggested the soil at the base presence of younger aeolian deposits, including ACT deposits.<br>Harksen (1968) and Briggs (1974) suggested the soil at the base<br>of these deposits correlated with the Sangamon Geosol that is Harksen (1968) and Briggs (1974) suggested the soil at the Sangamon Geosol widely preserved in the North American midcontinent.<br>Widely preserved in the North American midcontinent. these deposits correlated with the Sangamon Geosol that is<br>dely preserved in the North American midcontinent.<br>In an earlier paper, White (1960) argued that the ACT deposits

widely preserved in the North American midcontinent.<br>In an earlier paper, White (1960) argued that the ACT deposits<br>and multiple buried soils observed in upland situations in the bad-In an earlier paper, White (1960) argued that the ACT deposits<br>and multiple buried soils observed in upland situations in the bad-<br>lands were Holocene, based on the presence of archaeological eviand multiple buried soils observed in upland situations in the bad-<br>lands were Holocene, based on the presence of archaeological evi-<br>dence within the buried soils of the ACT deposits. White (1960) lands were Holocene, based on the presence of archaeological evidence within the buried soils of the ACT deposits. White (1960) also recognized the potential palaeoenvironmental significance of dence within the buried soils of the ACT deposits. White (1960) also recognized the potential palaeoenvironmental significance of the ACT record and hypothesized that periods of buried soil features of the solution of the also recognized the potential palaeoenvironmental significance of the ACT record and hypothesized that periods of buried soil formation represented relatively mesic climatic conditions. In conthe ACT record and hypothesized that periods of buried soil<br>formation represented relatively mesic climatic conditions. In con-<br>trast, he thought that periods of more active aeolian accumulation<br> $W^{1/2}$ formation represented relatively mesic climatic conditions. In contrast, he thought that periods of more active aeolian accumulation correlated with relatively xeric conditions. White (1960) further trast, he thought that periods of more active aeolian accumulation<br>correlated with relatively xeric conditions. White (1960) further<br>suggested that a regional correlation of these postglacial aeolian correlated with relatively xeric conditions. White (1960) further suggested that a regional correlation of these postglacial aeolian deposits might be possible. In this paper, we test the hypotheses of previous workers who deposits might be possible. In this paper, we test the hypotheses deposits might be possible. In this paper, we test the hypotheses<br>of previous workers who have studied ACT deposits in the White<br>River Badlands. Detailed stratigraphic, pedologic and geochronolof previous workers who have studied ACT deposits in the White<br>River Badlands. Detailed stratigraphic, pedologic and geochronol-<br>ogic investigations allow us to infer the timing of aeolian activity River Badlands. Detailed stratigraphic, pedologic and geochronologic investigations allow us to infer the timing of aeolian activity<br>in this area and compare the chronology to others in the Great Plains.

#### Study area

The water<br>contents used for the dose-rate calculations were the field values,<br>with an uncertainty that should encompass the extremes at  $\pm 2\sigma$ .

#### **Stratigraphy**

All sections examined contain buried soils formed in fluvial, aeolian or colluvial sediments that are overlain by ACT deposits. All sections examined contain buried soils formed in fluvial, aeolian or colluvial sediments that are overlain by ACT deposits.<br>These lowest-buried soils are typically  $\sim 7900$  <sup>14</sup>C yrs BP at ian or colluvial sediments that are overlain by ACT deposits.<br>These lowest-buried soils are typically ~7900 <sup>14</sup>C yrs BP at higher-elevation tables, and ~2900 <sup>14</sup>C yrs BP at lower tables These lowest-buried soils are typically  $\sim$ 7900<sup>-14</sup>C yrs BP at lower tables higher-elevation tables, and  $\sim$ 2900<sup>-14</sup>C yrs BP at lower tables (Figure 2). ACT sediments typically have loam and sandy-loam and sandy-loam higher-elevation tables, and  $\sim$ 2900<sup>-14</sup>C yrs BP at lower tables<br>(Figure 2). ACT sediments typically have loam and sandy-loam<br>textures with dominantly very fine sand, 0.5–1% organic carbon (Figure 2). ACT sediments typically have loam and sandy-loam textures with dominantly very fine sand,  $0.5-1\%$  organic carbon and  $0.5-5\%$  CaCO<sub>3</sub>. Sand ranges from 32 to 85%, and occasional textures with dominantly very fine sand,  $0.5-1\%$  organic carbon<br>and  $0.5-5\%$  CaCO<sub>3</sub>. Sand ranges from 32 to 85%, and occasional<br>(<1%) pebbles occur where coarse grains are located downslope and 0.5–5% CaCO<sub>3</sub>. Sand ranges from 32 to 85%, and occasional  $(<1\%)$  pebbles occur where coarse grains are located downslope and are hence available for transport by wind gusts. However,  $(<1\%)$  pebbles occur where coarse grains are located downslope<br>and are hence available for transport by wind gusts. However,<br>some ACT deposits on Cuny Table contain over 50% pebbles<br>above the shallowest, probably late-Hol and are hence available for transport by wind gusts. However, some ACT deposits on Cuny Table contain over 50% pebbles above the shallowest, probably late-Holocene, buried soil. Hetu (1992) also documents ACT deposits that are coarser than typical deposits. The ACT deposits are thought to be aeolian (1992) also documents ACT deposits that are coarser than typical aeolian deposits. The ACT deposits are thought to be aeolian because they are located at cliff edges at the highest point in the located because they are de aeolian deposits. The ACT deposits are thought to be aeolian because they are located at cliff edges at the highest point in the landscape, are restricted to within 10–15 m of cliff edges, and only contain pebble-size grai because they are located at cliff edges at the highest point in the the cliff face (Figure 3). Thickness of the ACT deposits and numonly contain pebble-size grains where they are exposed lower in<br>the cliff face (Figure 3). Thickness of the ACT deposits and num-<br>ber of buried A-C and A-AC-C soils within them vary, although the cliff face (Figure 3). Thickness of the ACT deposits and num-<br>ber of buried A-C and A-AC-C soils within them vary, although<br>late-Holocene soils from several localities have average ages of<br> $\sim$ 1300,  $\sim$ 2500 and  $\sim$ 3 late-Holocene soils from several localities have average ages of  $\sim$ 1300,  $\sim$ 2500 and  $\sim$ 3700<sup>-14</sup>C yrs BP (Figure 2). The 1300<sup>-14</sup>C yr BP soil is cumulic, with a thicker and lighter A horizon. Above ~1300, ~2500 and ~3700 <sup>14</sup>C yrs BP (Figure 2). #### Norbeck Pass ( $\sim$ 850 m elevation)

The section described at Norbeck Pass is the northernmost **Norbeck Pass (~850 m elevation)**<br>The section described at Norbeck Pass is the northernmost<br>sampled section (Figure 1). The site is different in that it is located<br>and the side of the site of the summary higher than the s The section described at Norbeck Pass is the northernmost<br>sampled section (Figure 1). The site is different in that it is located<br>on a ~100 m wide ridge, rather than a several kilometre wide sampled section (Figure 1). The site is different in that it is located<br>on a  $\sim$ 100 m wide ridge, rather than a several kilometre wide<br>table, and there is no soil developed in the sediments underlying on a  $\sim$ 100 m wide ridge, rather than a several kilometre wide table, and there is no soil developed in the sediments underlying CaCO<sub>3</sub>. Overlying this is 190 cm of ACT deposits with loam and the ACT deposits. The stratigraphy includes an approximately 20 cm thick pebbly clay loam with 0.3% organic carbon and 8.4% CaCO<sub>3</sub>. Overlying this is 190 cm of ACT deposits with loam and clay loam textures, 0.5 to 1.6% o cm thick pebbly clay loam with  $0.3\%$  organic carbon and  $8.4\%$ CaCO<sub>3</sub>. Overlying this is 190 cm of ACT deposits with loam and<br>clay loam textures, 0.5 to 1.6% organic carbon and no CaCO<sub>3</sub>.<br>There are two buried soils with A-C profiles in the ACT deposits. clay loam textures, 0.5 to 1.6% organic carbon and no CaCO<sub>3</sub>.<br>There are two buried soils with A-C profiles in the ACT deposits.<br>The lowest has an age of  $3654 \pm 42^{14}$ C yr BP (AA-39200) and The lowest has an age of  $3654 \pm 42$  <sup>14</sup>C yr BP (AA-39200) and the uppermost has an age of 1333  $\pm$  38<sup>-14</sup>C yr BP (AA-39199).

#### **Discussion**

**Discussion**<br>Although both the thickness of the ACT deposits and the number of soils buried in them vary among sections, a clear chronological Although both the thickness of the ACT deposits and the number<br>of soils buried in them vary among sections, a clear chronological<br>pattern of landscape stability is apparent between soil develop-

ment and contrasting aeolian accumulation. On the bases of the  $\sim$ 10000 <sup>14</sup>C yr BP age at the Nellie East section, ACT sediments ment and contrasting aeolian accumulation. On the bases of the  $\sim$ 10000<sup>-14</sup>C yr BP age at the Nellie East section, ACT sediments probably accumulated throughout the Holocene and during the leads  $\sim$ 10000<sup>-14</sup>C yr BP age at the Nellie East section, ACT sediments<br>probably accumulated throughout the Holocene and during the<br>late Pleistocene. However, these early Holocene ACT sediments probably accumulated throughout the Holocene and during the<br>late Pleistocene. However, these early Holocene ACT sediments<br>and buried soils are preserved only on the higher (950 m) tables<br>(Figure 3) late Pleistocene. However, these early Holocene ACT sediments<br>and buried soils are preserved only on the higher (950 m) tables<br>(Figure 3). At the sections studied at this elevation, the oldest and buried soils are preserved only on the higher (950 m) tables<br>(Figure 3). At the sections studied at this elevation, the oldest<br>soils are developed in deposits other than ACT sediments. On (Figure 3). At the sections studied at this elevation, the oldest<br>soils are developed in deposits other than ACT sediments. On<br>Cuny Table, ACT deposits overlie well-sorted dune sands above<br>funciol argued by the political M soils are developed in deposits other than ACT sediments. On Cuny Table, ACT deposits overlie well-sorted dune sands above fluvial gravels, but on Sheep Mountain Table ACT deposits are above interbedded gravel and very fin Cuny Table, ACT deposits overlie well-sorted dune sands above fluvial gravels, but on Sheep Mountain Table ACT deposits are<br>above interbedded gravel and very fine sand/coarse silt. On Cuny<br>Table, the lowest-buried soil has an age of  $\sim 7900$  <sup>14</sup>C yrs BP at above interbedded gravel and very fine sand/coarse silt. On Cuny<br>Table, the lowest-buried soil has an age of  $\sim$ 7900<sup>-14</sup>C yrs BP at<br>three sections, which is close in age to the cold event between<br> $7.650 \div 100$ Table, the lowest-buried soil has an age of  $\sim$ 7900 <sup>14</sup>C yrs BP at three sections, which is close in age to the cold event between 7650 and 7200 <sup>14</sup>C yrs BP (the so-called '8200 yr event') recorded three sections, which is close in age to the cold event between 7650 and 7200<sup>14</sup>C yrs BP (the so-called '8200 yr event') recorded in Greenland ice cores (Alley *et al.*, 1997). This is also a time 7650 and 7200<sup>14</sup>C yrs BP (the so-called '8200 yr event') recorded<br>in Greenland ice cores (Alley *et al.*, 1997). This is also a time<br>when closed-basin lakes to the east switch from fresh to saline<br>(Fritz *et al.*, 2000). in Greenland ice cores (Alley *et al.*, 1997). This is also a time<br>when closed-basin lakes to the east switch from fresh to saline<br>(Fritz *et al.*, 2000). It is tempting to correlate these events, but the when closed-basin lakes to the east switch from fresh to saline<br>(Fritz *et al.*, 2000). It is tempting to correlate these events, but the<br>lowest-buried soil at Sheep Mountain Table has an age some-<br>where between 5000 and (Fritz *et al.*, 2000). It is tempting to correlate these events, but the lowest-buried soil at Sheep Mountain Table has an age somewhere between 5800 and 6900  $^{14}C$  yrs BP, which is much later lowest-buried soil at Sheep Mountain Table has an age somewhere between 5800 and 6900<sup>-14</sup>C yrs BP, which is much later then the aforementioned events. Probably, the early-Holocene where between 5800 and 6900<sup>-14</sup>C yrs BP, which is much later<br>then the aforementioned events. Probably, the early-Holocene<br>ACT record is incomplete because of high badland erosion rates then the aforementioned events. Probably, the early-Holocene<br>ACT record is incomplete because of high badland erosion rates<br>(Hadley and Schumm, 1961), and requires more work before such<br>recording to the such that ACT record is incomplete b<br>(Hadley and Schumm, 1961)<br>correlations can be tested.<br>The late Halo record Alley and Schumm, 1961), and requires more work before such<br>rrelations can be tested.<br>The late-Holocene record, however, is more complete, probably

correlations can be tested.<br>The late-Holocene record, however, is more complete, probably<br>because there has been less time to erode it. In the late Holocene,<br>ACT sedimentation occurred in periods after ~3700, ~2500 and The late-Holocene record, however, is more complete, probably<br>because there has been less time to erode it. In the late Holocene,<br>ACT sedimentation occurred in periods after ~3700, ~2500 and<br>~1300 <sup>14</sup>C yr BP (Figure 5). ACT sedimentation occurred in periods after ~3700, ~2500 and ~1300 <sup>14</sup>C yr BP (Figure 5). Based on ages from the bottom of the 1300 <sup>14</sup>C yr BP soil at Sheep Mountain and Cuny Table, the latest of latest ~1300<sup>-14</sup>C yr BP (Figure 5). Based on ages from the bottom of the 1300<sup>-14</sup>C yr BP soil at Sheep Mountain and Cuny Table, the latest aeolian episode occurred after several centuries of cumulic

Figure 5 Late-Holocene periods of aeolian sedimentation (AS) and pedogenesis. Only age estimates from the top 5 cm of buried soils are pedogenesis. Only age estimates from the top 5 cm of buried soils are included here because they represent a maximum age of burial by aeolian sedimentation. Radiocarbon ages are plotted against section location; SMT <sup>=</sup> Sheep Mountain Table; NP <sup>=</sup> Norbeck Pass; BT <sup>=</sup> Bouquet Table; F <sup>=</sup> Frieda; N <sup>=</sup> Nellie; NW <sup>=</sup> Nellie West.

soil formation. The luminescence ages agree well with the radisoil formation. The luminescence ages agree well with the radio<br>carbon chronology at Sheep Mountain Table (Figure 3; Table 2) ocarbon chronology at Sheep Mountain Table (Figure 3; Table 2) and could be used to resolve the chronology of aeolian sedimenocarbon chronology at Sheep Mountain Table (Figure 3; Table 2)<br>and could be used to resolve the chronology of aeolian sedimen-<br>tation further. However, it is likely that these deposits accumulate and could be used to resolve the chronology of aeolian sedimentation further. However, it is likely that these deposits accumulate continuously, albeit slowly, because there are no soil horizons dural paral in the social m tation further. However, it is likely that these deposits accumulate<br>continuously, albeit slowly, because there are no soil horizons<br>developed in these sediments at the modern surface and there is continuously, albeit slowly, because there are no soil horizons<br>developed in these sediments at the modern surface and there is<br>typically a metre of aeolian sediment burying the uppermostdeveloped in these sediments at the modern surface and there is<br>typically a metre of aeolian sediment burying the uppermost-<br>buried soil. The late-Holocene record presented here compares<br>well with the magnetized in the int typically a metre of aeolian sediment burying the uppermost-<br>buried soil. The late-Holocene record presented here compares<br>well with those mentioned in the introduction in that there is eviburied soil. The late-Holocene record presented here compares well with those mentioned in the introduction in that there is evidence for episodic Holocene aeolian activity. The periods of soil well with those mentioned in the introduction in that there is evidence for episodic Holocene aeolian activity. The periods of soil formation seem to correlate quite well with nearby localities that dence for episodic Holocene aeolian activity. The periods of soil<br>formation seem to correlate quite well with nearby localities that<br>have well-constrained age control, especially Wolfe *et al.* (2000) formation seem to correlate quite well with nearby localities that<br>have well-constrained age control, especially Wolfe *et al.* (2000)<br>and Goble *et al.* (2001). These periods are also similar to millenhave well-constrained age control, especially Wolfe *et al.* (2000) and Goble *et al.* (2001). These periods are also similar to millennial-scale climate cycles in the North Atlantic (Bond *et al.*, 1997; 2001).

#### Conclusion

Just as with other studies of Holocene aeolian deposits from the Just as with other studies of Holocene aeolian deposits from the Great Plains, the White River Badlands ACT deposits provide Just as with other studies of Holocene aeolian deposits from the<br>Great Plains, the White River Badlands ACT deposits provide<br>evidence of episodic aeolian sedimentation. It appears that these<br>vidence for episodic aeolian se Great Plains, the White River Badlands ACT deposits provide<br>evidence of episodic aeolian sedimentation. It appears that these<br>deposits formed over most of the Holocene, including the lowest<br>reliance including the lowest evidence of episodic aeolian sedimentation. It appears that these deposits formed over most of the Holocene, including the lowest soil previously thought to correlate to the Sangamon Geosol deposits formed over most of the Holocene, including the lowest<br>soil previously thought to correlate to the Sangamon Geosol<br>(Harksen, 1968; Briggs, 1974). Our data support White's (1960) soil previously thought to correlate to the Sangamon Geosol (Harksen, 1968; Briggs, 1974). Our data support White's (1960) hypothesis that the age of the buried soils in the ACT deposits hypothesis that the age of the buri (Harksen, 1968; Briggs, 1974). Our data support White's (1960)<br>hypothesis that the age of the buried soils in the ACT deposits<br>are consistent throughout this subregion of the North American hypothesis that the age of the buried soils in the ACT deposits<br>are consistent throughout this subregion of the North American<br>Great Plains, probably as a result of climatic influence. These are consistent throughout this subregion of the North American<br>Great Plains, probably as a result of climatic influence. These<br>ACT deposits are a valuable source of palaeoenvironmental Great Plains, probably as a result of climatic influence ACT deposits are a valuable source of palaeoen proxy, as others most likely are in similar settings.
