Old stands of bromegrass for pasture or hay--apply 80-120 pounds of nitrogen per acre

* Inoculation of the legume seed with reliable cultures is desirable.
** 40 pounds of additional available phosphate per acre for each year the legume is to occupy the land. Plenty of phosphate is especially recommended on limy soils.
*** On sandy, strongly acid, or limy soils where plenty of available nitrogen is present, corn sometimes responds profitably to phosphate applied at planting time.
**** On irrigated or badly deficient fields, apply 60-80 pounds of nitrogen per acre.
Farmers trying commercial fertilizers for the first time should place an unfertilized strip a rod or two wide in the middle of the field, in order to observe by direct comparison whether it pays to use the fertilizer. A careful estimate of the yield of fertilized and unfertilized strips should be made, by weighing or measuring the crop harvested from equal areas if possible. An increase of 5 bushels of grain or 0.5 ton of hay is usually profitable, but is not easily seen in the field.

The drill or other implement used for applying fertilizer should be thoroughly cleaned and oiled at the end of each day's work. If this is not done, the working parts will rust and may become so caked with fertilizer that the machine will not work at all.

Soil tests will help you to find out the lime and fertilizer needs of a particular field or soil area. Supplies and instructions for taking soil samples should be obtained at the county agent's office.

Time and Method of Application

A. Phosphate Fertilizers

1. Small grains: The phosphate fertilizer should be applied at the time of planting with a combination drill. Some kinds of superphosphate may be mixed with the seed and the mixture drilled with the ordinary grain drill. Broadcasting the phosphate fertilizer is not recommended for wheat, nor for spring grains seeded without a legume.

2. Corn: Using an attachment on the lister or planter, place the phosphate in the row close to the seed but not in contact with it.

3. Legumes: Broadcast and disk into soil just before planting. Stands of alfalfa which are one or two years old may be topdressed without tillage.

4. Grasses: Drill in with seed, or broadcast fertilizer and disk just before seeding. On established stands of grass it usually does not pay to apply phosphate except for the purpose of bringing in a stand of clover.

B. Nitrogen Fertilizers

1. Corn or grain sorghums: Best applied with an attachment on the cultivator at the second or third cultivation. The nitrogen fertilizer may be broadcast between the rows prior to the second cultivation. Nitrogen at planting time is much less effective than later, except that anhydrous ammonia at or just before planting seems to get good results.

2. Wheat: Broadcast in the fall before or after seeding or in the spring before the grain is 6 inches tall. Later spring application results in higher protein in the grain but smaller increase in yield.
3. Oats and barley: Broadcast at planting or before the crop is 6 inches high.

4. Bromegrass pasture: Broadcast in the fall (October or November) or early in spring, preferably before the end of March.

5. Bromegrass seed production:
   Solid stands: Broadcast in the fall (October or November) or early spring (before March 15).
   Rows: Apply in the fall with an attachment on the cultivator or broadcast in the fall as a topdressing. Early spring broadcasting usually gets good results, but sometimes brings on serious weed competition. Early spring application with cultivator attachment would be all right if done early enough (before March 15).

C. Mixed Fertilizers

1. Small grains: Mixed fertilizers supplying the recommended amount of phosphate and 10 pounds or less of nitrogen per acre may be applied with the seed at planting time with a combination grain fertilizer drill. Additional nitrogen should be supplied either before seeding or before the grain is 6 inches tall.

2. Corn and sorghums: Experiments with phosphate or mixed fertilizers on corn at planting time show little or no increase in yield in most cases. But the starter fertilizer usually produces faster early growth. It may permit easier weed control. The phosphate in the starter fertilizer usually causes earlier and more uniform maturity. It may be worth while for these reasons. Therefore you should compare results with and without starter fertilizer on corn (20 to 30 lb of available P₂O₅, with or without 6 to 12 pounds of nitrogen). The starter should be applied in the row close to the seed but not in contact with it, by means of attachments on the planter or lister.

D. Lime

Much of the flat upland in Eastern Nebraska needs lime for successful growth of legumes. Before seeding alfalfa or clover, soil samples should be tested, and lime applied if the test shows a deficiency. The lime should be spread several weeks or months before seeding, especially for sweetclover and red clover. It should be disked in, or plowed under if not plowed too deep.

E. Potash

The soils of Nebraska are usually well supplied with potash. Experimental plots over the state with commercial fertilizers show that potash usually does not pay on most crops, except in isolated fields where the soil is sandy, acid, and deficient in potash.
