1. A review has been made of the RIG: "Computation of Outflow from Breached Dams (Draft)." The Military Hydrology and Hydraulics Division is to be complimented on such a lucid presentation of a very complex subject.

2. As a result of our review, two comments are offered:

a. Effect of tailwater submergence on discharge: the RIG uses Villanotte's sharp-crested weir formula while the flow might be expected to resemble that common to a broad-crested weir. If so, the coefficients will differ from those assumed.

b. The RIG does not mention the breaching phenomena associated with an earth-dam. A paragraph or two might be included which would summarize the current state of the art and perhaps make recommendations for the study of this very important phase of the dam-breach problem.

ENGINEER INTELLIGENCE GUIDE

COMPUTATION OF OUTFLOW FROM BREACHED DAMS

This document was compiled by the Army Map Service and has been approved by the Chief of Engineers for dissemination within the Corps of Engineers. This document has not been reviewed by the Office of the Assistant Chief of Staff for Intelligence, and therefore does not necessarily represent agreed Department of the Army guidance.

Printed by Army Map Service

PREFACE

Engineer Intelligence Guides (EIG's) are the media for the dissemination of intelligence collection, processing, production, and dissemination guidance by the Chief of Engineers to pertinent elements of the Corps of Engineers. EIG's are designed to provide orientation, direction, and instruction in the field of Engineer intelligence. Comments on this EIG and suggestions for additional EIG's are solicited from all recipients. Comments and suggestions should be addressed to:

Chief of Engineers
Department of the Army
Washington 25, D. C.
ATTN: Area Analysis Division

Note: the ATTENTION line was changed from "Intelligence Division" with correction tape.

ABSTRACT

The failure or demolition of high dams, impounding large volumes of water, may release large flood waves capable of seriously damaging downstream military and civilian installations and of disrupting river crossings and other military operations. The outflow from a breached dam is influenced by the dimensions of the breach, the volume and shape of the reservoir, tailwater conditions, reservoir inflow, and other variables. The theoretical and experimental equations used to compute the breach outflow in civilian practice are very complex and too time-consuming for military use. Simplified step-by-step procedures for determining the flow through the breach are developed in this study to permit fairly rapid prediction of the breach outflow hydrograph with a degree of accuracy acceptable for military situations. Computation procedures with illustrative examples are given for three types of breach: 1) a small breach with the size and shape of the breach and the total reservoir storage governing the outflow; 2) a medium breach with a steep negative wave in the reservoir significantly affecting outflow; and 3) a large breach with tailwater submergence, as well as the factors previously listed, affecting outflow.
