Abstract

Two non-interpenetrated zirconium metal−organic frameworks (Zr-MOFs), NPF-200 and NPF-201, were synthesized via the assembly of elongated tetrahedral linkers with Zr$_6$ and Zr$_8$ clusters. They represent the first examples of MOFs to have the $\beta$-UH$_3$-like, 4,12,12T1 topology. Upon activation, NPF-200 exhibits the largest BET surface area (5463 m$^2$ g$^{-1}$) and void volume (81.6%) among all MOFs formed from tetrahedral ligands. Composed of negative-charged boron-centered tetrahedral linkers, NPF-201 is an anionic Zr-MOF which selectively uptakes photoactive [Ru(bpy)$_3$]$^{2+}$ for heterogeneous photo-oxidation of thioanisole.

The past two decades have witnessed the rapid development of metal–organic frameworks (MOFs) as a class of highly porous crystalline materials. The tunability of both organic linkers and inorganic metal cluster based secondary building units (SBUs), combined with large surface areas and convenient chemical modification methods, has enabled potential applications of MOFs in areas such as gas storage and separation, catalysis, chemical sensing, and drug delivery, among others. Since many MOFs are water/moisture-sensitive due to the reversible coordination bonding, considerable effort has been focused on MOFs with high thermal and chemical stability for their ultimate practical applications. Zirconium-based MOFs (Zr-MOFs) represent a remarkable improvement to this end: the high valence of Zr$^{IV}$ and large Zr$^{IV}$−O bond polarization can lead to a strong bonding between
Zr$^{IV}$ and carboxylate oxygens in the ligands. Since the discovery of UiO-66 in 2008, Zr-MOFs with rich structural types, outstanding chemical stability, and intriguing properties and functions have made significant progress. Nevertheless, this specific type of MOF is still in its early stage of development. Its wider practical applications call for continuous discovery of new structures with novel topologies, which is important to understanding the fundamental correlation between framework structure and porosity, stability, and interpenetration.

Tetrahedral ligands are inherently three-dimensional, fully extended linkers that have received considerable attention in recent years. However, to date there are only five Zr-MOFs composed of tetrahedral ligands. Four of them, including MOF-841 and PCN-521, have the non-interpenetrated flu topology (CaF$_2$, fluorite), which can be considered as the “pseudo”-cubic close packing of the 8-connected Zr$_6$ clusters, where the octahedral cavity is void space and all the tetrahedral interstitial cavities are occupied by tetrahedral ligands (Figure 1a). During the synthesis of MOF-841, Yaghi et al. also discovered MOF-812 as a byproduct, which is essentially a 4,12-connected net of a rare 6-connected net of a rare 4,12-center packed topology. This topology can be viewed as the body-centered packing of 12-connected Zr$_6$ clusters, where half of the tetrahedral interstitial cavities are occupied by tetrahedral ligands (Figure 1b). Although little study has been performed on MOF-812, its discovery does reveal the possibility for new topologies of Zr-MOFs based on other tetrahedral linkers.

Herein, we report two non-interpenetrated Zr-MOFs, NPF-200 and NPF-201 (where NPF means Nebraska Porous Framework), based on elongated tetrahedral linkers (Figure 1c). Both MOFs belong to the rare 4,12,12T1 topology. Importantly, NPF-200 can be successfully activated and exhibits 81.6\% solvent-accessible volume and a BET surface area of 5463 m$^2$g$^{-1}$, which is the largest among the MOFs formed from tetrahedral ligands and also the third largest among all Zr-MOFs. Additionally, the isostructural NPF-201, featuring a tetravalent boron-centered linker, is an anionic Zr-MOF that selectively uptakes [Ru(bpy)$_3$]$^{2+}$.

The two tetrahedral linkers, L$_4$ and L$_5$, were synthesized by Sonogashira coupling, followed by saponification in basic aqueous solution (see Supporting Information (SI), section S-3, for detailed procedures). Colorless crystals of NPF-200 [Zr$_6$(μ$_3$-O)$_4$(μ$_3$-OH)$_4$][Zr$_8$(μ$_2$-O(H))$_{12}$](L$_4$)$_{12}$ were obtained via a solvothermal reaction of ZrCl$_4$ with L$_4$ in N,N-dimethylformamide (DMF) with benzoic acid as modulating agent at 120 °C for 48 h. Single-crystal X-ray diffraction reveals that NPF-200 crystallizes in the cubic space group Pm3n, consistent with the truncated octahedral shape of the single crystals (SI, Figure S7). The experimental powder X-ray diffraction (PXRD) patterns of NPF-200 are in excellent agreement with the simulation (Figure 2a), demonstrating the material’s bulk purity.
NPF-200 is a non-interpenetrated framework that is composed of two different types of 12-connected Zr clusters (Zr₆ and Zr₈) linked by tetrahedral ligands (Figure 1c). Overall, it is a trinodal net with the 4,12,12T1 topology with point symbol (4̂28.6̂32.8̂9)3(4̂30.6̂30.8̂6)6(4̂6)12, which is the same observed for that of β-UH₃.⁺ It is noteworthy that NPF-200 represents the first MOF structure that exhibits this rare topology. The Zr₆ and Zr₈ clusters in NPF-200 can be envisioned as the topological close packing phase A₁₅ (Figure 1d),¹¹ one of the Frank–Kasper phases used to describe the structures of intermetallics with A₃B stoichiometry (e.g., Nb₃Sn)¹² and certain self-assembled macro-molecules.¹³ In a typical cubic unit cell, B atoms (as Zr₈ clusters in NPF-200) occupy the body-centered cubic sites while a pair of A atoms (as Zr₆ clusters in NPF-200) occupy the face-centered sites, further linking in infinite chains along the [100], [010], and [001] directions. Therefore, Zr₆ clusters in NPF-200 lie in the center of the 12-fold distorted icosahedron (as B atoms in A₁₅), and Zr₈ clusters lie in the center of a 14-fold Kasper polyhedron (as A atoms in A₁₅) (Figure 1e). Each tetrahedral ligand is connected with three Zr₆ clusters and one Zr₈ cluster (Figure 1e), just like the H-atoms in β-UH₃. (Figure 1d). Since the A₁₅ phase has exclusively tetrahedral interstices (see SI, section S-7, for detailed description), NPF-200 can also be considered, as part of its tetrahedral interstitial cavities are occupied by tetrahedral ligands (Figure 1e). On average, 24 tetrahedral ligands occupy 46 interstitial tetrahedra in each unit cell, giving rise to a 52.2% occupancy compared to 50% in MOF-812. Further, five well-defined cages with sizes ranging from 12 to 20 Å can be identified in NPF-200 (Figure 1f and SI, Figures S15–S19).

The Zr₆ cluster in NPF-200 is the commonly observed, 12-connected Zr₆(μ₃-O)₄(μ-OH)₄ in many Zr-MOFs (i.e., UiO-66 and its isoreticular fcu series⁵), which can be simplified as a cuboctahedron (SI, Figure S20). In contrast, the Zr₈ cluster in NPF-200 is best described as Zr₈(μ₂-O(H))₁₂, with eight Zr atoms connecting 12 μ₂-O(H), forming a cubic Zr cluster in which the eight vertices are occupied by Zr atoms capped by 12 μ₂-O(H) occupying the edges (Figure 1c, see SI, section S-2, for details). The simplified Zr₈ cluster in NPF-200 corresponds to a slightly distorted icosahedron (SI, Figure S21), which nevertheless is more regular compared to that of the Zr₆ clusters in MOF-812 (SI, Figure S20), likely due to the coordination of four monodentate carboxylate groups in the latter. In NPF-200, each Zr atom in the Zr₈ cluster coordinates with three μ₂-O(H) and three oxygen atoms from carboxylates, forming a distorted octahedral coordination geometry. Compared to the Zr₆ cluster, the Zr₈ cluster is much less common. Zhou et al. previously reported an example of cubic Zr₈ cluster, Zr₈(μ₄-O)₆(OH)₁₀, in PCN-221, where each edge of the Zr₈ cube is bridged by a carboxylate group, and the simplified SBU corresponds to a cuboctahedron with O₈ symmetry (SI, Figure S21).¹⁴ Our result represents the second example of Zr₈ cluster in Zr-MOF.
The thermal stability of NPF-200 was assessed by thermogravimetric analysis. The high decomposition temperature around 450 °C reveals the excellent thermal stability of the material at elevated temperature (SI, Figure S25). NPF-200 shows remarkable stability in acidic and basic conditions (Figure 2b). After soaking in aqueous solutions with pH values ranging from 1 to 11 (prepared with HCl and NaOH respectively) for 24 h, the PXRD patterns of NPF-200 are almost unchanged, suggesting the preserved crystallinity (Figure 2b). The N\textsubscript{2} adsorption of NPF-200 after water treatment (SI, Figure S11) exhibits only a minimal deviation from that of the pristine sample, indicating the framework is highly robust. However, NPF-200 does start to lose crystallinity after being soaked in a strongly basic solution (pH 12) (Figure 2b).

Supercritical CO\textsubscript{2} exchange\textsuperscript{15} was employed to activate NPF-200 to avoid channel collapse. With a pore volume of 2.17 cm\textsuperscript{3}g\textsuperscript{−1}, NPF-200 has N\textsubscript{2} uptake at 77 K of 1403 cm\textsuperscript{3}g\textsuperscript{−1}, \(S_{\text{BET}}\) (Brunauer–Emmett–Teller surface area) of 5463 m\textsuperscript{2}g\textsuperscript{−1}, and \(S_{\text{Langmuir}}\) (Langmuir surface area) of 6877 m\textsuperscript{2}g\textsuperscript{−1}. Based on the calculated value by PLATON, the solvent-accessible volume is 81.6\%.\textsuperscript{16} It is noted that NPF-200 has the largest surface area, pore size, and solvent-accessible volume among all MOFs constructed from tetrahedral ligands. The calculated volumetric surface area of NPF-200 is 2125 m\textsuperscript{2}cm\textsuperscript{−3}, which is outstanding among many well-known MOFs (SI, Table S3). For certain gas uptake applications, a large volumetric surface area is crucial.\textsuperscript{17}

Isoreticular expansion\textsuperscript{18} is a useful strategy to increase the pore size and surface area for Zr-MOFs.\textsuperscript{19} It is, however, interesting to note that the ligand elongation in NPF-200 did not result in the expected flu topology as in PCN-521. The increased rotational freedom from \(L_3\) (in PCN-521) to \(L_4\) (in NPF-200) likely plays a role here. In order to fulfill the coordination and topological requirement in NPF-200 (i.e., binding with one \(Zr_6\) and three \(Zr_8\) clusters in 4,12,12T\textsubscript{1} topology), the tetrahedral ligand \(L_4\) needs to adopt a \(C_{2v}\) symmetry so that the two peripheral benzoates are perpendicularly orientated to one pseudo-mirror plane and two peripheral benzoates lying in the other (Figure 3a). Such conformation is made possible by the triple-bond spacer between the two phenyl rings that promotes low to no torsional barrier for the vicinal phenyl rings.\textsuperscript{20} Indeed, other conformations of \(L_4\) are possible, as exemplified in MOF Cu\textsubscript{2}L\textsubscript{4} reported by Lin et al., where all four peripheral benzoates are perpendicularly orientated to the mirror planes (Figure 3b).\textsuperscript{7f} Conversely, in PCN-521, all four peripheral benzoates of \(L_3\), which has \(D_{2d}\) symmetry, lie in the two mirror planes to meet the requirement of coordination to four \(Zr_6\) clusters in the flu topology (Figure 3c). Further, in the absence of spacer, the reduced rotational freedom between the two phenyl rings in \(L_3\) makes it unfavorable to adopt a zero dihedral angle, which is required to adopt a conformation similar to that of \(L_4\) to form the 4,12,12T\textsubscript{1} topology.

The success in synthesizing NPF-200 offers a general way of constructing non-interpenetrated Zr-MOFs with exceptional high porosity. We next set out to synthesize an isostructure of NPF-200 using a boron-centered
tetrahedral linker $L_5$ (Figure 1d; see SI, section S-2, for synthetic details) that has essentially the same size and dimensionality as $L_4$. Since $L_5$ is inherently negatively charged, the resulting MOF is expected to be an anionic Zr-MOF. Both single-crystal XRD (SI, section S-4) and the PXRD pattern (Figure 2a) show that the product from the solvothermal reaction of $\text{ZrCl}_4$ and $L_5$, called NPF-201, is isostructural with NPF-200. However, activation of NPF-201 was not successful, and $S_{\text{BET}}$ of NPF-201 was only 534 m$^2$g$^{-1}$, probably due to the framework collapse induced by the extraframework counterion, tetra-n-butylammonium. Nevertheless, NPF-201 still exhibits good thermal stability (thermal decomposition temperature of 400 °C, SI, Figure S26) and chemical stability in solution (SI, Figure S10), which enable its potential applications in the solvated state, including heterogeneous catalysis.

The anionic charge of the framework of NPF-201 was further confirmed by dye exchange experiments. As expected, NPF-201 does not adsorb the anionic dye, acid orange 7, but strongly adsorbs the cationic methylene blue (Figure 4a). The adsorbed methylene blue can be further exchanged by soaking in 0.5 M $\text{NH}_4\text{Cl}$ solution (Figure 4a). To the best of our knowledge, NPF-201 represents the first example of anionic Zr-MOF.\textsuperscript{21} This feature opens enormous opportunities to incorporate functional cationic guests into Zr-MOFs for a variety of applications.\textsuperscript{22} Here, a photoactive cationic transition metal complex, $[\text{Ru-}(\text{bpy})_3]^{2+}$, was incorporated into NPF-201 via ion exchange to form Ru@NPF-201 (Figure 4b,c). The loading level of $[\text{Ru(bpy)}_3]^{2+}$, 0.37 Ru complex per ligand, was determined using NMR spectroscopy of an acid-digested sample (SI, Figure S8). This loading value is close to the ideal uptake (0.5 per ligand), suggesting the successful incorporation of the metal complex inside the framework. Ru@NPF-201 exhibits the characteristic emission band of $[\text{Ru(bpy)}_3]^{2+}$ at 600 nm (Figure 4d) and can be used as a heterogeneous catalyst in photooxidation of thioanisole. Indeed, while NPF-201 does not show any activity at all, Ru@NPF-201 gives rise to the sulfoxide product in an excellent yield (98%), with a catalytic activity comparable to that of $[\text{Ru(bpy)}_3]^{2+}$, indicating that the reaction is not diffusion limited (SI, section S-9 and Table S2). Importantly, Ru@NPF-201 exhibits excellent recyclability: after five times of reuse, no decrease of catalytic activity is observed (SI, Table S2).

In summary, we have synthesized two new non-interpenetrated Zr-MOFs with the rare $\beta$-$\text{UH}_3$-like, $4,12,12T1$ topology using elongated tetrahedral linkers. NPF-200 exhibits high permanent porosity (2.17 cm$^3$g$^{-1}$), large surface area (5463 m$^2$g$^{-1}$), and exceptional stability, which make it a promising candidate material for gas storage. Anionic NPF-201 successfully incorporates photoactive $[\text{Ru(bpy)}_3]^{2+}$ via cation exchange, and the resulting hybrid material exhibits good photocatalytic activity and recyclability toward the photo-oxidation of thioanisole. Our work points to a new direction for designing functional Zr-MOFs with new topologies using elongated tetrahedral linkers.
