areas of partially realigned, somewhat linearly arrayed muscle fibers. Figure 2 shows a 40 min, 400 rpm extruded pork chop sample also containing slightly realigned muscle fibers with areas that appear to contain emulsion-like, less-ordered material. This emulsion-like material is probably the desinewed pork shank meat which filled in the gaps between muscle fibers during the restructuring and extrusion process. The apparent non-realignment of the muscle fibers of desinewed shank meat may be explained by its smaller particle size (1/4" in diameter) compared to the diameter (1/2") of the extruding horn. Particle sizes smaller than the diameter of the extruding horn may not be forced to flow in a "one way" direction resulting in little realignment of muscle fibers.

Figure 3 is a micrograph from a 40 min, 200 rpm extruded pork chop sample which indicates distinct areas of linearly arrayed muscle fibers composed of chunked pork loin blade meat and emulsion-like, less-ordered areas containing desinewed pork shank meat. Figure 4 shows the well-ordered muscle fiber structure of an intact boneless pork chop control.

### Conclusion

Twin screw cold extrusion technology can be used to manufacture restructured meat products. Extruded pork chops manufactured from lower-valued pork loin blade meat and desinewed pork shank meat had desirable sensory and textural attributes which were equal to or better than the intact boneless pork chop control. Scanning electron microscopy of cooked extruded and control pork chop samples suggest that part of the reason for the desired textural attributes observed in extruded chops may be due to partial realignment of muscle fibers.

## Pharmacological Levels of Zinc in Nursery Diets - A Review

Duane E. Reese<sup>1</sup>

Zinc plays significant roles in pig nutrition and health. A zinc deficiency is manifested by skin lesions known as parakeratosis; poor feed intake; slow growth; diarrhea; and atrophy of the thymus, a gland important in immunological competence. Zinc ions may interact with *E. coli* by inhibiting the ability of *E. coli* to respire and therefore reducing its activity. In addition, recent University of Nebraska research indicates that zinc ions cause the organism responsible for swine dysentery (*S. hyodysenteriae*) to produce less toxin. On the other hand, too much zinc in the feed will cause growth depression, arthritis, and ultimately death.

Nutritionists typically add 100 to 150 ppm of zinc to nursery diets to meet requirements for growth. Recently there has been interest in feeding nursery pigs diets containing 2,000 to 4,000 ppm of zinc to combat postweaning stress and diarrhea.

A summary of research studies that have evaluated the response of nursery pigs to pharmacological levels of zinc is presented in Table 1. Added zinc levels ranged from 2,400 to 3,200 ppm. In all cases zinc oxide supplied the supplemental zinc. Percent changes in daily gain, daily feed intake, and feed/gain due to the pharmacological levels of zinc are shown along with the sig-

nificance level.

This summary indicates that the response to pharmacological levels of zinc is highly variable. For example, sometimes daily gain was increased by 25% whereas at other times gain was decreased by 28% compared to the control diets containing normal zinc concentrations. Similar wide ranges in response to zinc are evident with feed intake. When the incidence of diarrhea was measured, the additional zinc seemed to reduce the frequency of diarrhea.

The level of copper in the diet does not seem to have a consistent effect on the response to zinc. Large positive responses to zinc were observed at all levels of added copper, but more frequent positive responses were observed when dietary copper was low (8 to 22 ppm). Moreover, all the poor responses to zinc were observed when 200 to 250 ppm copper was added to the feed.

These results indicate that the decision to use pharmacological levels of zinc in nursery diets should be made on a case-by-case basis. Careful monitoring of pig performance when high levels of zinc are added to feed is warranted to be sure the right conditions exist for a response. Unfortunately, it is currently not possible to describe the conditions under which a positive response to extra zinc is likely.

<sup>C</sup>P<.06

Results within the boxes are from the same test. Cu = copper.

It is important to know whether positive responses to zinc are occurring on the farm. Otherwise, the practice of feeding extra zinc should be stopped because producers may be taking unnecessary risks, including causing pig performance to decline. Zinc is a heavy metal and it is not known how long-term application of manure from animals fed extra zinc will affect plants or the environment in general. Also, the effect on lagoon function is uncertain. Furthermore, high levels of zinc may interfere with iron metabolism so it is not clear what changes, if any, in iron fortification of diets is necessary.

### Recommendations

There obviously can be benefits to feeding pharmacological levels of zinc to nursery pigs. However, until further research is conducted to determine the conditions under which a positive response to pharmacological levels of zinc is likely, the performance of pigs fed high zinc levels be closely monitored. The best way to do this is to conduct an on-farm trial. Details on how to conduct an on-farm feed trial properly are available in the University of Nebraska publication *Conducting Pig Feed Trials on the Farm* (EC 92-270-B). Single copies are available for

\$.50 at any extension office in Nebraska. Out of state residents should contact Bulletins, P.O. Box 830918 Lincoln, NE 68583-0918.

It is important that the extra zinc be supplied by zinc oxide until further research with other sources is reported. Add 2,500 to 3,000 ppm (7.0 to 8.3 lb of zinc oxide/ton of complete feed assuming the zinc oxide contains 72% zinc) to feed for 14 d postweaning only. Add 6 to 15 ppm copper to the diet.
