PREPARATION OF FUNCTIONALIZED POLYMERS UTILIZING A SOLUBLE HIGHLY REACTIVE FORM OF CALCIUM

Reuben D. Rieke
ABSTRACT

Calcium-substituted polymeric reagents are provided. These reagents can be prepared via the oxidative addition of a soluble highly reactive calcium species to organic and inorganic polymers containing alkyl, aryl, or alkylaryl pendant groups substituted with halide atoms, cyano or pendant nitrogen, 1,3-dienes, or any conjugated polyunsaturated system. Preferably, the polymer is a cross-linked p-bromopolystyrene, p-chloropolystyrene, p-fluoropolystyrene, or chloromethylpolystyrene. Preferably, the soluble highly reactive calcium species is prepared from the reduction of Ca(II) salts with an alkali metal arene, such as lithium biphenylide. These calcium-substituted polymeric reagents react with a variety of electrophiles to yield functionalized polymers. Reaction with Cu(I) salts yields calcium-substituted polymeric cuprate reagents, which can react, for example, with acid chlorides to form ketones, alkyl halides containing functionality, and undergo 1,4-conjugate addition with α,β-unsaturated ketones, aldehydes, esters, and amides. Bifunctionalization of the polymer can be achieved by the addition of highly reactive calcium to a functionalized polymer containing a halogen. Polymers can be cross-coupled with dyes, UV stabilizers, biologically active substrates, molecules that impart specifically desired characteristics, among other desirable functional groups.

PREPARATION OF FUNCTIONALIZED POLYMERS UTILIZING A SOLUBLE HIGHLY REACTIVE FORM OF CALCIUM

The present invention was made with Government support under Contract No. GM35153 awarded by the National Institute of Health. The Government has certain rights in the invention.

BACKGROUND OF THE INVENTION

Polymers permeate every aspect of today's society. Moreover, advances in our society are keenly tied to advances in new materials, particularly polymers. Unfortunately, however, we are limited in the types of polymers that can be prepared. For example, polymers containing a wide variety of desirable functional groups can not be prepared, or if they can be prepared, it is only with great difficulty. Thus, using presently known techniques it is generally difficult to modify polymers. For example, it is typically difficult to modify the surfaces of polymers to attach dyes, UV stabilizers, molecules that impart conducting properties, magnetic properties, non-linear optical properties, etc.

Furthermore, insoluble polymers, such as cross-linked polystyrene resins and functionalized polystyrene resins, are highly desirable reagents in organic synthesis. For example, insoluble polymers are important reagents in organic synthesis as protecting groups and in asymmetric syntheses as chiral auxiliaries. They are also important reagents in solid-phase synthesis, and as supports for chromatography and catalysis.

Methods for chemically modifying polymers, i.e., functionalizing polymers, such as cross-linked polystyrene resins, typically involve: (1) lithiation of p-bromopolystyrene; (2) lithiation of polystyrene; and (3) nucleophilic substitution on chloromethylated polystyrene. These transformations of insoluble polymers normally occur with a soluble reagent interacting in intimate fashion with an insoluble polymer. This occurs, for example, in the preparation of lithium and potassium derivatives of chloromethylated polystyrene. Furthermore, insoluble Grignard reagents have been prepared in THF from the addition of a soluble magnesium anthracene to lightly cross-linked polymers containing chloromethyl groups and alkyl/aryl bromides. These reagents, however, have limited applicability.

The use of functionalized polymers in organic chemistry, particularly those containing metal atoms, has been slowed by the insoluble form in which most metals are typically found. Thus, there are relatively few effective techniques available to prepare functionalized polymers, particularly containing metal atoms.

An object of this invention is to generate novel functionalized polymers, both soluble and insoluble, that may not be available using standard polymerization techniques. Furthermore, an object of this invention is to develop a method for modifying the surfaces of soluble and insoluble polymers to attach dyes, UV stabilizers, drug systems, biologically active substrates, molecules that impart conducting properties, magnetic properties, nonlinear optical properties, adhesive properties, thermal stability, or increased strength. Another object of this invention is to produce a wide variety of calcium-substituted polymeric reagents that can be used to produce new organic compounds, new functionalized polymers, and new, more direct methods of synthesis. Yet another object of this invention is to produce a wide variety of calcium-substituted polymeric reagents that can be used to produce novel polymers, which upon cleavage can be used to synthesize novel monomers and organic products.

SUMMARY OF THE INVENTION

These and other objects are achieved by the present invention, which is directed to the use of a soluble highly reactive calcium species to form calcium-substituted polymeric reagents, which can be either substantially organic polymers or substantially inorganic polymers. As used herein, the phrase "highly reactive" refers to the reactivity of the calcium species in organic reactions, particularly oxidative addition reactions. A calcium species is highly reactive if it reacts with a wide variety of primary, secondary, and particularly tertiary alkyl halides in relatively high yields, for example in greater than about 50% yields, preferably in greater than about 70% yields.

A polymer that is "substantially" organic is one in which the main polymer backbone, or internal support structure, is composed of organic repeating structural units. A polymer that is "substantially" inorganic is one in which the main polymer backbone, or internal support structure, is composed of inorganic repeating structural units.

The polymers useful in the compounds and methods of the present invention can be soluble or insoluble, preferably they are insoluble. They can be in the form of beads, pellets, films, blocks, or powders, without limitation. They can be solvent swellable, macroreticular, or popcorn polymers, without limitation. They can be noncross-linked, i.e., linear, lightly cross-linked, or highly cross-linked. They can be organic polymers of any of a variety of monomers, such as styrene, butadiene, divinylbenzene, vinyl chloride, etc. They can be inorganic polymers, such as alumina or silica. Preferably, the polymers are insoluble organic polymers. More preferably, they are insoluble olefinic-based polymers, i.e., polymers made from olefinic monomers. Most preferably they are insoluble polystyrene-based polymers.

According to the invention, the polymers contain groups that react with the soluble calcium species irrespective of whether the polymers are substantially inorganic or substantially organic. These reactive groups can be within, or attached directly to, the polymer backbone or support structure, or they can be within or attached to groups pendant to the main polymer backbone. The reactive groups include organic or other groups preferably substituted with halogen, cyanide, 1,3-dienes, or conjugated polysaturated hydrocarbon systems.

The soluble highly reactive calcium species used to prepare the calcium-substituted polymeric reagents of the present invention is composed of formally zervalent calcium metal atoms in combination or complexation with a solubilizing agent in an ethereal, polyether, or hydrocarbon solvent. The solubilizing agent can be any of a variety of macrocyclic polyethers, cypretates, or polynes capable of interacting with the formally zervalent calcium metal atoms in such a manner that a less reactive finely divided powder does not substantially precipitate out of solution. Preferably, the solubilizing agent is a polyeze. More preferably, the solubilizing agent is an aromatic polyeze, i.e., an arene or polarylene, such as an aromatic electron-transfer compound. Examples of aromatic electron-transfer compounds include biphenyl, naphthalene, and anthra-
The soluble activated calcium species can also be in combination with an alkali metal salt.

The calcium-substituted polymeric reagents are in their most general sense polymers containing calcium atoms, either within, or attached directly to, the backbone of the polymer or within, or attached to, groups pendant therefrom. Preferably the polymers contain aliphatic, aryl, arylalkyl, or heterocyclic pendant groups substituted with calcium. The calcium-substituted polymeric reagents can also have pendant aliphatic, aryl, arylalkyl, or heterocyclic groups substituted with halogen, cyanide, 1,3-diene, or conjugated polyunsaturated groups that did not react with the highly reactive calcium species, as well as groups unreactive to the highly reactive calcium species. Thus the calcium-substituted polymeric reagent of the present invention can include a polymer containing reactive halogen, cyanide, 1,3-diene, or conjugated polyunsaturated groups, and at least one of these reactive groups further substituted with a calcium atom.

The calcium-substituted polymeric reagents undergo subsequent reaction with a variety of electrophiles to form functionalized polymers. They also undergo reactions with a variety of Cu(II) salts to yield calcium-substituted polymeric cuprate reagents. These polymers, which consist of a polymer in combination or complexation with calcium and copper atoms, in turn can be used to carry out a number of useful transformations on the polymer. Significantly, methods and reagents of the present invention can be used to introduce a second functional group into a polymer which contains a halogen as well as another functional group.

In the context of this invention, the term "aliphatic" means a saturated or unsaturated linear, branched, or cyclic hydrocarbon radical. The term "heterocyclic" means a mono- or polynuclear cyclic radical containing carbons and one or more heteroatoms such as nitrogen, oxygen, or sulfur or a combination thereof in the ring or rings, including but not limited to pyridine, pyrrole, indole, thiazole, pyrazine, furan, cytosine, thymine, adenine, uracil, oxazoles, pyrazoles, hydantoin, piperezine, quinoline, xanthene, 1,10-phenanthroline, and acridine. The term "aryl" means a mono- or polynuclear aromatic hydrocarbon radical. The term "arylalkyl" means a linear, branched, or cyclic alkyl hydrocarbon radical having a mono- or polynuclear aromatic hydrocarbon or heterocyclic substituent.

The term "polymeric" or "polymer" is used herein in its most general sense to mean a compound consisting essentially of repeating structural units. It refers to inorganic polymers such as silica and alumina. It also refers to organic polymers such as polyolefins, polyesters, polysaccharides, polyamides, polycarbonates, polyethers, etc.

**Detailed Description of the Invention**

The present invention is based upon the discovery that a soluble highly reactive calcium metal species displays surprising and unexpected reactivity and usefulness in the functionalization and modification of polymers, particularly the surfaces of insoluble polymers. The soluble highly reactive calcium species displays surprising and unexpected reactivity toward a wide variety of polymers, including organic and inorganic polymers containing reactive groups such as halide atoms, cyanide molecules, 1,3-dienes, or any conjugated polyunsaturated system. By using the interaction between the highly reactive calcium species of the present invention and the reactive groups within the polymer, either within the polymer backbone or pendant thereto, new polymers can be produced, for example, by modifying known polymers, particularly the surfaces of known soluble and insoluble polymers, to attach dyes, UV stabilizers, indicators, drug systems, biologically active substrates, and molecules that impart conducting properties, magnetic properties, nonlinear optical properties, adhesive properties, thermal stability, or increased strength.

**The Polymers**

The polymers that can be functionalized, or modified especially with respect to their surface characteristics, by the methods of the present invention can be soluble or insoluble. They can be in the form of beads, powders, pellets, films, or blocks, without limitation. They can be solvent swellable, macroreticular, or popcorn polymers, without limitation. They can be noncrosslinked, i.e., linear, lightly cross-linked, i.e., with about 1-3% cross-linking, or highly cross-linked, i.e., with about 15-20% cross-linking reagents.

The polymers that can be functionalized, or modified especially with respect to their surface characteristics, by the methods of the present invention can be substantially organic or substantially inorganic. They can be organic polymers prepared from monomers of styrene, butadiene, divinylbenzene, vinyl chloride, tetrafluoroethylene, and the like. They can be inorganic polymers, i.e., solid supports based on alumina, silica, clay, zeolites, glass, and the like.

In general, any of a variety of soluble or insoluble polymer materials, whether substantially organic or inorganic based, containing a group reactive with the soluble calcium species can be functionalized by the methods of the present invention. These groups reactive with the soluble calcium species of the present invention include halide atoms, cyanide molecules, 1,3-dienes, or any conjugated polyunsaturated system. These groups can be within, i.e., attached directly to, the polymer backbone, such as in a polyvinylchloride polymer, or polymer or a polytetrafluorethylene polymer. They can also be within or attached to organic groups pendant to the polymer backbone, such as in a polystyrene polymer. Preferably, these reactive groups are within, or attached to, aliphatic, heterocyclic, aryl, or arylalkyl groups pendant to the polymer backbone.

If an inorganic support, such as alumina or silica, is used, the surface can be treated with reagents such as CICH₂CH₂CH₂Si(ΟEt)₃, for example, to form an alkyl chloride attached to the surface. The remainder of the Si—ΟH groups can be protected prior to reaction of the alkyl chloride with an electrophile. Subsequent to the reaction with an electrophile, the protecting group can be removed.

Preferably, the polymers useful in the reagents and methods of the present invention are insoluble organic polymers having pendant organic groups substituted with halogen, cyanide, 1,3-dienes, or conjugated polyunsaturated groups. More preferably they are insoluble olefinic-based polymers having aliphatic, aryl, aryalkyl, or heterocyclic pendant groups substituted with halogen, cyanide, 1,3-dienes, or conjugated polyunsaturated groups. Most preferably, the olefinic-based polymers, i.e., polymers made from olefinic monomers, are...
polystyrene resins containing halide moieties or C1-6 haloalkyl moieties. Of the C1-6 haloalkyl and halide moieties, the preferred groups include chloromethyl, fluoromethyl, bromomethyl, bromine, chlorine, iodine, and fluorine moieties. The most preferred groups include chloromethyl, bromine, chlorine, and fluorine.

The polymers can be characterized by the number of reactive groups within the polymer, i.e., either within the polymer backbone or within a group pendant thereto. This characterization can be reported as the degree of substitution, degree of functionality, or degree of functionalization. Similarly, these values can be used to characterize the modified, i.e., functionalized, polymer with respect to the desired functionality.

The degree of substitution of the desired polymer starting materials with, for example, halide groups is preferably within a range of about 1-98 halide atoms attached per 100 aromatic or pendant chains (0.5-8.0 mmole halide atoms per gram polymer). More preferably, the degree of substitution is within a range of about 1-15 halide atoms attached per 100 aromatic or pendant chains (0.5-1.5 mmole halide atoms per gram polymer), and most preferably about 1-6 halide atoms attached per 100 aromatic or pendant chains (0.5-1.0 mmole halide atoms per gram polymer).

The degree of functionality (DF), i.e., the degree of functionalization (DF), of polystyrene polymers, for example, represent the fraction of aromatic rings that possess the desired functionalities. The desired polymer starting materials possess a DF within a range of about 0.01-1.0, more preferably within a range of about 0.10-0.25, and most preferably within a range of about 0.10-0.15. This is simply another means by which the degree of substitution of the polymers, whether the desired polymer starting materials or the resultant modified or functionalized polymers, can be characterized.

Polystyrene, a preferred organic polymer, is a high molecular weight linear polymer represented by the formula [CH(C6H5)CH2]n. The commercially useful form of polystyrene is amorphous and highly transparent. It is stiff and clear at room temperature, and a viscous liquid above its glass-transition temperature. The basic polymer backbone is chemically inert. Styrene can be copolymerized with a variety of other monomers, including butadiene, methyl methacrylate, methacryloyl acetone, divinylbenzene, and the like, to effect its characteristics. Divinylbenzene copolymers with styrene are typically used as supports for the active sites in ion exchange resins.

Polystyrene is available in a wide variety of cross-link densities, surface areas, and porosities. The polystyrene resins useful in the present invention are preferably lightly cross-linked polystyrene/divinylbenzene resins. By cross-linking, it is meant that the polymer chains are interconnected by means of a —(CH2CH2)— group attached to the aryl ring system. The degree of cross-linking is preferably within a range of about 1-3%, more preferably within a range of about 1-2%, and most preferably at about 1%. For polystyrene/divinylbenzene, this value is given in terms of “DVB,” i.e., the amount of divinylbenzene. The degree of cross-linking effects the solubility of the polymers. The more highly cross-linked, the more insoluble the polymer is in most solvents.

The polymers, particularly insoluble polymers, can swell in certain solvents to expose or open reactive sites or make these sites available for reaction with the reactive calcium species. Each polymer can swell to a different extent depending on the solvent used. This interaction between polymers and solvents is generally well known to those skilled in the art of polymer chemistry and depends on the polarity of the solvent, structure of the polymer, etc. This interaction can be used to modify the amount of functionalization, or modification, that occurs by the methods of the present invention. For example, in benzene, toluene, and THF, 1% cross-linked polystyrene resin is fully swollen and allows easy penetration of the calcium species. In cyclohexane, however, the resin is only partially swollen. For partially swollen polymers, there are a number of reactive sites located in pores that are inaccessible to the calcium species. Thus, the degree of modification of polymers, particularly insoluble polymers, can be effected by the proper choice of solvent system. That is, the extent to which the surface of a polymer, or more of the main polymer matrix or bulk of the polymer can be modified is, to some extent, dependent on the solvent chosen for the reaction.

The physical form of the polymer also effects the extent to which the polymer can be functionalized. For example, polymer powders are readily penetrated by solvents and can be functionalized to a significant extent throughout the main polymer matrix. Large block polymers are not so easily penetrated. Thus, the degree of functionalization will be substantially concentrated on the surface of the polymer, rather than throughout the main polymer matrix or bulk of the polymer.

The extent to which a polymer is cured can also affect the degree of functionalization. For example, a thermoset polymer can be derivatized by the methods of the present invention before it is cured and while it is still flexible. It can then be cured to form a highly derivatized polymer, both on the surface and within the main polymer matrix or bulk of the polymer.

Also envisioned to be within the scope of the present invention are methods whereby a polymer can be functionalized by the soluble highly reactive calcium and then cleaved to get functionalized monomers. Furthermore, the extent of cross-linking within a polymer can be increased by using the soluble highly reactive calcium species.

The Soluble Highly Reactive Calcium Species

Soluble highly reactive calcium can be added to a polymer, and particularly to an olefinic-based polymer substituted with halogen, cyanide, 1,3-dienes, or conjugated polyunsaturated groups to form calcium-substituted polymeric reagents. The calcium-substituted polymeric reagents, i.e., calcium-substituted polymers, can be either soluble or insoluble; preferably they are insoluble. They can undergo a variety of reactions with organic electrophiles to produce both novel functionalized polymers and novel synthetic methods for new and known organic compounds under relatively mild reaction conditions.

The soluble highly reactive calcium species used to prepare the calcium-substituted polymeric reagents of the present invention is composed of formally zera-vental calcium metal atoms in combination or complexation with a solubilizing agent. By "formally zera-vental" it mean that the formal oxidation state, or charge, is equal to the group number (i.e., 2) minus the number of unshared electrons (i.e., 2) minus the number of bonds (i.e., 0). Although the formal oxidation state of the calcium metal in the preferred highly reactive calcium species is considered to be zero, it is believed that
there is significant charge transfer between the calcium and the solubilizing agent. The solubilizing agent that is in combination or complexion with the formally zerovalent calcium species preferably comes from a corresponding solubilized reducing agent that is capable of reducing Ca(II) salts in an ethereal, polyethereal, or hydrocarbon solvent. The solubilizing agent can be any of a variety of macrocyclic polyethers, crown ethers, cryptates, polyenes, and the like, capable of interacting with the formally zerovalent calcium metal atoms in such a manner that a less reactive finely divided powder does not precipitate out of solution to any significant extent. By this it is meant that the formally zerovalent calcium species of the present invention is substantially completely soluble in an ethereal, polyethereal, or hydrocarbon solvent with only about 20% or less of the calcium species in a solid state, i.e., in which there is no significant interaction with the solubilizing agent.

Preferably, the solubilizing agent is a polyene. More preferably, the solubilizing agent is an aromatic polyene, i.e., an arene or polyarylene, such as an aromatic electron-transfer compound. Examples of aromatic electron-transfer compounds include, but are not limited to, biphenyl, napthalene, and anthracene. Compounds such as these are typically capable of transferring electrons in an oxidation reduction reaction through the formation of radical anions.

Thus, in a preferred embodiment, the highly reactive calcium species of the present invention is composed of zerovalent calcium metal atoms in combination or complexion with one or more of the arenes napthalene, anthracene, or biphenyl. More preferably, the highly reactive calcium species of the present invention is composed of zerovalent calcium metal atoms in combination or complexion with the arene biphenyl.

The highly reactive calcium species of the present invention, whether in a mixture or complex, is soluble in ethereal, polyethereal, or hydrocarbon solvents. These include, but are not limited to, ethyl ether, tetrahydrofuran, glyme, diglyme, triglyme, benzene, and the like. If a hydrocarbon solvent is used, it preferably contains a secondary solubilizing agent such as N,N,N',N'-tetramethylethylenediamine, or other diamine or bidentate ligand capable of solubilizing the starting materials and product, particularly the starting materials. Preferably, the highly reactive calcium species is soluble in an ethereal or polyethereal solvent. More preferably, it is soluble in tetrahydrofuran (THF).

The soluble highly reactive calcium species can also be in combination with an alkali metal salt wherein the anion does not contain an acidic proton. The alkali metal of the salt can be Li, Na, K, Rb, or Cs. Preferably, it is Li, Na, or K, and most preferably it is Li. The anion can be, but is not limited to, a nitrate, nitrite, sulfate, cyanide, or halide. Preferably, the anion is a halide or cyanide. More preferably, the anion is a halide, and most preferably the anion is bromide or iodide.

The most specific and preferred embodiment of the soluble highly reactive calcium species of the present invention is composed of zerovalent calcium metal atoms in combination with, or complexed with, biphenyl and a lithium halide. The solvent used to solubilize the most preferred embodiment of the calcium species is tetrahydrofuran (THF).

The soluble highly reactive calcium species of the present invention is prepared from the reduction of a calcium(II) salt, the counterion of which can be any of a variety of anions that does not contain an acidic proton. For example, the anion can be a sulfate, nitrate, nitrite, cyanide, or halide. Preferably, the anion is a cyanide or a halide. More preferably, the anion is F, Cl, Br, or I. Most preferably the anion of the Ca(II) salt is Br or I.

Generally, the reducing agent can be any solubilized reducing reagent that is capable of reducing Ca(II) salts in an ethereal, polyethereal, or hydrocarbon solvent. Any reducing agent having a reduction potential of about −1.5 volts or more negative will satisfy this relation. It is preferred, however, if the reducing agent has a reduction potential of about −1.8 volts or more negative, and most preferred if the reducing agent has a reduction potential of about −2.0 volts or more negative.

Examples of suitable solubilized reducing agents include alkali metal salts of aromatic anions, such salts being, for instance, sodium or lithium naphthalenide, anthracenide, or biphenylide; alkali metal-polyether solvates; alkali metal-crown ether solvates; alkali metal-cryptate solvates, and the like. Preferably, the reducing agent is an alkali metal arene salt. More preferably, the reducing agent is a combination of an alkali metal cation and an anion of an aromatic electron transfer compound, such as biphenyl, anthracene, or napthalene. Most preferably, the reducing agent is preformed. Of the preformed alkali metal arene salts, the most preferred is lithium biphenylide.

By "preformed" it is meant that the alkali metal and about 1–1.2 equivalents of the arene are allowed to react substantially completely, i.e., until substantially all the alkali metal is consumed, before contacting any calcium salts. The formation of the preformed reducing agent typically takes place in an ethereal, polyethereal, or hydrocarbon solvent, and generally is substantially complete in about 2 hours.

Because the soluble highly reactive calcium species is preferably utilized within a short period of time after its preparation, it can also contain the alkali metal salt produced from the cation of the reducing agent and the anion of the calcium salt starting material. Generally, the alkali metal salt is not believed to effect the reactivity of the highly reactive calcium; however, it may facilitate the reactivity, particularly the oxidative addition reactions, of the polymeric organic halides with the highly reactive calcium.

The process for reduction to produce the soluble highly reactive calcium species is conducted under conditions designed to prevent its reoxidation and substantial precipitation as calcium powder. Generally, these conditions include use of ethereal, polyethereal, or hydrocarbon solvents and the exclusion of oxygen. Also, conditions are controlled so as to promote the existence of the calcium atoms as small soluble clusters and to avoid their agglomeration into larger configurations that could precipitate out of solution. Larger clusters of metal atoms generally mean lower solubility and lower reactivity.

Preferably, these conditions include temperatures of about 100 °C. or less, an inert atmosphere, e.g., an argon or nitrogen atmosphere, a reaction time of about 1 hour, and an ether or polyether solvent such as diethyl ether, dimethyl ether, tetrahydrofuran and the like, or a hydrocarbon solvent. The Ca(II) salt can be soluble in the solvent of the reaction, or it can be a suspension therein. The Ca(II) salt is preferably soluble in the solvent at room temperature, as is the resultant soluble highly
reactive calcium species. The reduction can as well be conducted in a hydrocarbon solvent with N,N,N',N'-tetramethylethylenediamine (TMEDA) to solubilize or disperse the starting material complex and reducing agent. Typically, the molar ratio of the reducing agent to the Ca(II) salt is about 2:1 for an equivalent amount; however, the Ca(II) salt can be in excess. Preferably, the Ca(II) salt is present in an amount of about 1.5–2.0 equivalents, and more preferably in an amount of about 1.5–2.0 equivalents, per equivalent of reducing agent. Excess Ca(II) salt is used to ensure that there is little or no reducing agent present during subsequent reactions, particularly if the highly reactive calcium is used in the subsequent reactions without previous isolation.

Although the zerovalent calcium species can be maintained for a time under these conditions, it is also quite reactive. Consequently, it is preferably synthesized and used immediately or within a very short period of time. However, it can be stored for several days and much longer at lower temperatures under an inert atmosphere.

The Calcium-Substituted and Calcium-Cuprate Polymeric Reagents and Reactions Thereof

The soluble highly reactive calcium species described above undergoes reaction with soluble and insoluble organic and inorganic polymers. These polymers contain groups reactive with the soluble calcium species. Preferably, these polymers contain reactive halogen, cyanide, 1,3-diene or conjugated polyunsaturated groups. Although a number of reactions are possible, preferably, the highly reactive calcium species undergoes oxidative addition to bromide, chloride, iodide, and fluoride-containing polymers. The products of these reactions, i.e., the insoluble calcium-substituted polymeric reagents, can then react with a variety of electrophiles to yield functionalized polymers.

The calcium-substituted polymeric reagents are in their most general sense polymers substituted with calcium atoms. They are preferably polymers with pendant aliphatic, aryl, arylalkyl, or heterocyclic groups substituted with calcium atoms. They can also have pendant aliphatic, aryl, arylalkyl, or heterocyclic groups substituted with halogen, cyanide, 1,3-diene, and conjugated polyunsaturated groups, or such groups with, or directly attached to, the polymer backbone. Preferably, the calcium-substituted polymeric reagents of this invention are aliphatic, aryl, heterocyclic, arylalkyl based polymeric calcium-substituted reagents, derived from the foregoing highly reactive calcium species. Although the exact nature of these reagents is not known, they may involve coordination or complexation with the solvent or lithium ions.

For the polymers containing 1,3-diene or other conjugated polyunsaturated groups, the mechanistic aspects of the addition of calcium involve the transfer of the calcium atom with its two valence electrons to the 1,3-diene or conjugated polyunsaturated system. For the polymers containing halogen or cyanide groups, the mechanistic aspects of the reactions involve an oxidative addition of the highly reactive calcium species to the carbon-halide or carbon-cyanide bond. For example, the mechanism of the oxidative addition reaction of the calcium species to the halide compounds involve the addition of calcium atoms into the aryl-halide or alkyl-halide bond of the polymers. Thus, there is loss of halide atoms directly bonded to the polymer. Although the halide atoms are shown intimately associated with the calcium atoms, this is not necessarily the situation as the halide atoms may be dissociated, as in an ionic manner. The calcium-halide groups, or just calcium groups, are then replaced by the organic radicals of the electrophiles. See the examples shown in Schemes I and II.

The calcium-substituted polymeric reagents, preferably insoluble reagents, of the present invention are generally formed using an equivalent amount or an excess of the highly reactive calcium species based on the amount of the reactive substituent, e.g., the halogen, in the polymer. Preferably, the highly reactive calcium is used in an amount of about 1.0–5.0 equivalents, more preferably about 1.5–3.0 equivalents calcium, and most preferably about 1.5–2.5 equivalents calcium per equivalent of reactive group or substituent. Upon the formation of the calcium-substituted polymeric reagent, the excess highly reactive calcium is typically removed from the polymer before further reactions are conducted.

As shown in Example 2 and Table I, the transformation to an insoluble calcium-substituted reagent can occur quantitatively under a variety of reaction conditions. The preferred conditions of the reaction are typically chosen to reduce the amount of cross-linking. The calcium is typically added to the polymers under an inert atmosphere, such as nitrogen or argon. The temperature of the reaction mixture is preferably within a
range of about -140°C to 100°C, more preferably within a range of about -80°C to 60°C, and most preferably within a range of about -45°C to 30°C, in order to reduce the amount of additional cross-linking that might occur. The reactions typically occur within about 0.1-120 hours.

The solvent in which the preparation of the calcium-substituted polymeric reagents is carried out can be an ethereal, polyether, or hydrocarbon solvent such as ethyl ether, tetrahydrofuran, glyme, diglyme, triglyme, benzene, and the like. As in the preparation of the soluble highly reactive calcium species, if a hydrocarbon solvent is used, it preferably contains a solubilizing agent such as N,N,N',N'-tetramethylethylene, or other diamine or bidentate ligand. Preferably, the solvent in which the calcium-substituted polymeric reagents are prepared is an ethereal or polyether solvent.

The insoluble calcium-substituted polymeric reagents described above can undergo reaction with a soluble Cu(I) salt, such as CuCN·2LiBr, CuI, CuBr, CuCl, CuF, lithium thiencyanocuprate, or other Cu(I) salts with nonprotic anions, to form new reagents with unique and different chemical reactivity and selectivity. These reagents are herein referred to as calcium-substituted polymeric cuprate reagents. Preferably, the Cu(I) salt used to prepare these calcium/copper reagents is CuCN·2LiBr or lithium thiencyanocuprate.

The reaction conditions used for the formation of the calcium-substituted polymeric cuprate reagents are those typically designed to preserve the integrity of the polymeric reagents. These conditions include the exclusion of water and oxygen, temperatures of less than about 100°C, preferably between about -140°C and about 100°C, and more preferably between about -80°C and about 30°C. The copper(I) salt is usually added in an equimolar amount relative to the amount of reactive substituents on the polymers prior to reaction with the highly reactive calcium species, but the copper(I) salt can be added in an excess amount. Preferably the copper(I) salts are added to the calcium-substituted polymeric reagents in an amount within a range of about 1.05 to 1.10 equivalents per equivalent of reactive group in the polymer prior to reaction with the calcium species.

Although, not intending to be limiting in any manner, it is believed that the copper is bound to a carbon on the polymer, and that the calcium may be in equilibrium with, or loosely coordinated with, the copper reagent. In general, the calcium enhances the reactivity of the organocopper reagent in subsequent reactions with electrophiles. Although not intended to be limited by theory, it is believed that the calcium atoms interact both with the copper and with the electrophile; however this is probably a function of the electrophile.

The calcium-substituted polymeric cuprate reagents are composed of a mixture or combination of an aliphatic, aryl, heterocyclic, arylalkyl polymeric calcium cuprate complexes and alkali metal salts. The alkali metal salts are from the copper(I) salt, which is preferably a thiencyanide, cyanide, or halide. More preferably it is a thiencyanide or a cyanide. Exemplary schematics of the formation of the calcium-substituted cuprate reagents using halide-substituted polystyrene resins are shown in Schemes III and IV.

The calcium-substituted polymeric reagents, as well as the calcium-substituted polymeric cuprate reagents, of the present invention can be isolated and stored at room temperature, under an inert atmosphere, without appreciable loss in reactivity. They can be stored for even longer periods of time if lower temperatures are used.

These calcium-substituted polymeric reagents and calcium-substituted cuprates undergo a variety of reactions with electrophiles. That is, these calcium-substituted polymeric reagents and calcium-substituted cuprates undergo a variety of reactions with compounds that are deficient in electrons, such as acid chlorides, ketones, aldehydes, nitriles, esters, amides, α,β-unaturated carbonyl compounds, epoxides, and the like. For example, the calcium-substituted polymeric cuprates undergo cross-coupling with acyl chlorides to generate ketones, reaction with functionalized halides, and 1,4-conjugate addition to α,β-unaturated carbonyl compounds, such as 2-cyclohexen-1-one, etc.

The electrophiles include, but are not limited to, D₂O, H₂O, CO₂, ClSiPh₃, ClFPh₃, CH₃O, CH₃CHO, ClSiMe₃, BrCH₂CH₂Br, C₅H₅O, CH₃COCl, p-ClC₆H₅COCl, CH₂COCl, Br(CH₂)₂CN, Br(CH₂)₂COEt, CH₂O₂, and ClSiMe₂, Cl₂SiPh₃, p-BrC₆H₅COCl. Using methods according to the present invention, and the above-listed electrophiles, polymers can be functionalized with any of the following substituents: -H, -D, -CH₃, -CH₂D, -COOH, -CH-.
by passage over a BASF™ R3-11 catalyst at 150°C, a phosphor pentoxide column, and a column of granular potassium hydroxide. Lithium ribbon (28 mm wide x 0.38 mm thick), biphenyl, naphthalene, or anthracone and CaCl₂ were weighed out and charged into reaction flasks under argon in a Vacuum Atmospheres Company drybox. Tetrahydrofuran was distilled from Na/K alloy under an argon atmosphere immediately before use. Technical grade wash solvents were used as received. Anhydrous calcium(II) iodide and bromide were purchased from Cerac, Inc., Milwaukee, Wis. Anhydrous calcium(II) chloride was purchased from Alfa Chemicals, Denver, Colo. All other reagents were used as received unless otherwise specified.

The degrees of functionalization (DF) and functional yields of the polymers represent the fraction of the polymer functionalized with the desired functionality. For polystyrene, they represent the fraction of aromatic rings that possess the desired functionalities. p-Bromopolystyrene was purchased from either Lancaster Synthesis, LTD (Windham, N.H., 2.44 mmol Br/g, DF=0.31, 2% DVB cross-linking, 200-400 mesh), or Fluka (Ronkonkoma, N.Y., 5.47 mmol Br/g, DF=0.98, 2% DVB cross-linking, 200-400 mesh). Chloromethylated polystyrene was purchased from either Kodak Chemicals (Rochester, N.Y., 1.06 mmol Cl/g, DF=0.11, 1% DVB cross-linking, 200-400 mesh), or Lancaster Synthesis, LTD (Windham, N.H., 5.50 mmol Cl/g, DF=0.80, 2% DVB cross-linking, 200-400 mesh). p-Chloropolystyrene (3.75 mmol Cl/g, DF=0.45, 3% DVB cross-linking, 200-400 mesh) and p-fluoropolystyrene (2.59 mmol F/g, DF=0.28, 3% DVB cross-linking, 200-400 mesh) were prepared from known literature procedures. See L. R. Melby et al., *J. Amer. Chem. Soc.*, 89, 450 (1967) for the analogous synthesis of iodo-polystyrene, which is incorporated herein by reference. In general, polyvinyl alcohol, styrene, p-halo styrene, divinyl benzene, and benzoyl peroxide in water are heated at 80°-90°C for 5 hours to form the snow-white bead polymer.

Acid-base titrations of the carboxylated polymers were performed following literature procedures. See L. Anand et al., *Macromol. Sym.* 4, 9 (1972) and M. J. Farrall et al. *J. Org. Chem.*, 41, 3877 (1976), which are incorporated herein by reference. The functional yield of the carboxylated polymer was based on acid-base titration. Low-temperature reactions were performed utilizing a Neslab Endocal™ ULT-80 refrigerated circulating bath or using dry ice/acetonitrite or acetone slush baths. Deuterium oxide (99.7%) was purchased from Fischer Scientific (Pittsburg, Pa.).

**EXAMPLE 1**

Preparation of Highly Reactive Calcium

Lithium (2.05 mmol) and biphenyl (2.46 mmol) were stirred in freshly distilled THF (15 mL) at room temperature under argon until the lithium was substantially completely consumed (approximately 2 hours). To a well-suspended solution of CaCl₂(1.00 mmol) in THF (15 mL), the preformed lithium biphenylide was transferred via a cannula at room temperature. The solution of highly reactive calcium was stirred for 1 hour at room temperature.
EXAMPLE 2

Preparation of Insoluble Calcium-Substituted Polymeric Reagents

An excess (i.e., 1.5-2.5 equivalents; starting halogen) of highly reactive calcium, prepared according to the procedure in Example 1, was added to lightly cross-linked (approximately 1-3%) polystyrene ("PS") resins containing halogen moieties (Br, Cl, F, CHCl2) at 0° C. or room temperature in THF under an inert atmosphere. Upon formation of the calcium-substituted polymeric reagent, the excess highly reactive calcium was removed from the polymer. As shown in Table I, the transformation to a calcium-substituted polymeric reagent can occur quantitatively under a variety of reaction conditions as evidenced by elemental analysis of the corresponding halogen after aqueous quenching. Preferably, the formation took place at room temperature or below in order to minimize any additional cross-linking that might occur. When the calcium-substituted reagents were prepared at 0° C. and isolated, red-brick colored solids were obtained while dark to medium brown colored solids were obtained when the reaction was carried out at room temperature. The reactivity of the corresponding calcium-substituted reagents were similar, and in many instances identical, in subsequent reactions. These reagents were stored under nitrogen at room temperature for about 1-2 months without noticeable loss in color. When exposed to air, the solids immediately decomposed and changed color. In the case of p-bromopolystyrene ("PS-Br"), the calcium-substituted reagent turned light tan while the chloromethylated polystyrene yielded a light yellow solid. Elemental analyses of the isolated calcium-substituted reagents confirmed the presence of calcium.

### EXAMPLE 3

Preparation of Insoluble Calcium-Substituted Polymeric Reagents from p-Bromopolystyrene and Reactions Thereof

The reaction of a 2% cross-linked p-bromopolystyrene with the soluble highly reactive calcium species to prepare the calcium-substituted reagent occurred almost quantitatively after 10 hours at 0° C. When the reaction was carried out at room temperature, 36 hours was needed for complete formation of the calcium-substituted reagent. The reaction was done without filtration of the excess highly reactive calcium from the polymer without significant detrimental effect to the functional yields. Reaction with CO₂(g) at ~45° C. followed by hydrolysis afforded the carboxylated product (Table II, entry 3) in 83% functional yield. The functional yield of the carboxylated polymer was based on acid-base titration. The yield is comparable to yields previously reported involving lithiation (80-95%) and Grignard formation (>70%) of p-bromopolystyrene.

The addition of triphenylchlorosilane with the calcium-substituted reagent gave the silylated product (Table II, entry 4) in 72% yield. The FTIR spectrum of the product showed the presence of strong peaks at 1248 and 758 cm⁻¹ corresponding to the Si-C bonds and the absence of the aryl bromide precursor at 1492, 1408, 1072, 1010, and 718 cm⁻¹. The calcium-substituted reagent underwent Grignard-type reactions with cyclohexanone and benzaldehyde to yield the corresponding tertiary and secondary alcohols, respectively. The latter reaction yielded the secondary alcohol in a quantitative yield (Table II, entry 7). The addition of chloromethylsilane (TMSCl) to the calcium-substituted reagent afforded the silylated product (Table II, entry 8) in a 43% yield. Addition of the TMSCl at various temperatures (i.e., ~45° C, 0° C, or room temperature) resulted in the same functional yields with no improvement observed at the lower temperatures or with longer reaction times.

The addition of a calcium species, prepared from Ca(acetate) and preformed lithium antracenediyl, to p-bromopolystyrene (DF = 0.31) at 0° C. for 10 hours and subsequent reaction with benzaldehyde at room temperature for 48 hours yielded the functionalized polymer in 80% yield. By elemental analysis, 98% Br was lost from the polymer. The dark calcium species appears to be reasonably soluble and may be a calcium antracene complex.

Preparation of PS-H

p-Bromopolystyrene (1.21 mmol Br, based on 2.44 mmol Br/g, DF = 0.31, 2% DVB cross-linking) was stirred in freshly distilled THF (30 mL) at room temperature for 24 hours prior to use. This was done for the purpose of swelling, i.e., unfolding or exposing, the polymer so as many of the Br groups as possible could be exposed to the highly reactive calcium. Highly reac-
5,211,886

5,211,886

tive calcium (3.02 mmol) was transferred via a cannula to the polymer at room temperature. The resulting dark solution was stirred for 48 hours at room temperature. At this time the polymer was filtered and washed with THF (15 mL). Fresh THF (30 mL) was added to the polymer and deionized water (15 mL) was added via a syringe. The solution was stirred for 44 hours at room temperature at which time the polymer was filtered and washed with 100 mL portions of H2O (2), THF (1), MeOH (1), acetone (1), and MeOH (1). The product was dried under vacuum for 24 hours at room temperature and yielded 0.3419 g of a light brown powder. FTIR (diffuse reflectance): peaks absent at 1492, 1407, 1070, 1008, and 718 cm⁻¹ for the aroyl bromide precurs-
or. Anal. Br=0.00.

Preparation of PS-D

Highly reactive calcium (2.82 mmol) was added to a solution containing p-bromopolystyrene (1.25 mmol Br) and stirred for 36 hours at room temperature. Deuteroxide oxide (5 mL) was added and stirred for 48 hours at room temperature. Isolation of the polymer yielded 0.5257 g of a light brown powder. FTIR: peak observed at 2255 cm⁻¹ for the D₂O bond. High resolution electron impact mass spectrometry (HR EI-MS) yielded fragments at 105.0695 m/e for C₇H₉D⁺ (10.36%), at 131.0859 m/e for C₁₀H₁₂⁺ (2.89%), and at 104.0623 m/e for C₈H₈⁺ (26.90%). Anal Br=0.00.

Preparation of PS-COOH

Highly reactive calcium (2.92 mmol) was added to a solution containing p-bromopolystyrene (1.17 mmol Br) and stirred for 48 hours at room temperature. Gaseous carbon dioxide was passed through a column of Drierite™ (anhydrous calcium sulfate available from Aldrich Chemical Co., Inc., Milwaukee, Wis.) and bubbled into the solution at −45 °C for 2 hours, 0 °C for 1 hour, and at room temperature for 1 hour. To this reaction mixture, 0.5 N HCl, THF, and MeOH. Drying yielded 0.3758 g of a tan powder. FTIR: peaks observed at 1733 and 1684 cm⁻¹ for the carboxyl group. Acid-base titrations yielded 2.03 mmol COOH/g or 83% functional yield. Anal Br=0.00.

Preparation of PS-SiPh₃

Highly reactive calcium (3.02 mmol) was added to a solution containing p-bromopolystyrene (1.19 mmol Br) and stirred for 40 hours at room temperature. Chlorotriphenylsilane (3.38 mmol) in THF (10 mL) was added and stirred for 50 hours at room temperature. Isolation and purification yielded 0.3419 g of a light brown powder. FTIR: observed peaks at 1248 and 758 cm⁻¹ for the Si—C bond. HR EI-MS yielded fragments at 259.0693 m/e for C₅H₉Si⁺ (3.40%), 130.0773 m/e for C₅H₅⁺ (3.21%), and 104.0625 m/e for C₄H₃⁺ (96.09%). Anal. calcd. for (C₅H₅O)₃Si(C₆H₄Si)₇(C₆H₄Si)₂.22, Si=3.82; Found: Si=3.58, Br=0.00. Functional yield =72%.

Preparation of PS-PPh₂

Highly reactive calcium (3.04 mmol) was added to a solution containing p-bromopolystyrene (1.20 mmol Br) and stirred for 48 hours at room temperature. Chlorodi phenylphosphine (6.15 mmol) in THF (10 mL) was added at 0 °C and stirred for 1 hour. The mixture was then warmed to room temperature over a period of 48 hours. A 3:1 mixture of acetone/H₂O (20 mL) was added to the polymer, which was then stirred for 4 hours at room temperature. Isolation and purification yielded 0.3590 g of a tan powder. FTIR: observed weak peaks at 1005, 1457 and 1492 cm⁻¹ for the P—Ar bonds. Anal. calcd. for (C₈H₇O)₃Si(C₆H₄O)₇(C₆H₄O)₂.22, P=4.69; Found: P=4.38, Br=0.00. Functional yield =71%.

Preparation of PS-C(OH)C₆H₄0

Highly reactive calcium (2.55 mmol) was added to a solution containing p-bromopolystyrene (1.04 mmol Br) in THF (30 mL) and stirred for 48 hours at room temperature. Cyclohexanone (5.67 mmol) in THF (10 mL) was added at −45 °C and the mixture was stirred for 1 hour. It was then allowed to warm to −45 °C to room temperature over a period of 70 hours. Water (20 mL) was added and the reaction mixture was stirred for 1 hour at room temperature. Isolation and purification yielded 0.2912 g of a tan powder. FTIR: observed sharp peak at 3643 cm⁻¹ for “free” OH stretch, broad OH stretch around 3460 cm⁻¹ for and the C—O stretch at 1028 cm⁻¹. HR EI-MS yielded fragments at 82.0792 m/e for C₆H₅OH (22.90%), 81.0721 m/e for C₆H₅OH (57.51%), 98.0733 m/e for C₆H₅OH (19.25%), 104.0627 m/e for C₆H₅OH (11.74%), and at 129.0767 m/e for C₆H₅OH (2.28%). Anal. calcd. for (C₆H₅O)₂C₆H₄OH (0.82%C₆H₅OH) 0.16, C=89.80, H=8.07, O=2.12; Found: C=89.85, H=7.46, O=1.89, Br=0.00. Functional yield =51%.

Preparation of PS-CH(OH)C₆H₄0

Highly reactive calcium (1.97 mmol) was added to a solution containing p-bromopolystyrene (1.31 mmol Br) in THF (30 mL) and stirred for 48 hours at room temperature. The polymer was filtered, fresh THF (30 mL) was added, and the mixture was cooled to −45 °C. Benzaldehyde (5.70 mmol) in THF (10 mL) was added at −45 °C and stirred for 4 hours. The mixture was allowed to warm to −45 °C to room temperature over a period of 48 hours. Water (20 mL) was then added to the polymer at −45 °C. The mixture was again allowed to warm to room temperature over a period of 24 hours. Isolation and purification yielded 0.3254 g of a tan powder. FTIR: observed sharp peak at 3641 cm⁻¹ for “free” OH stretch, broad OH stretch around 3400 cm⁻¹ and C—O stretch at 1027 cm⁻¹. Anal. calcd. for (C₆H₅O)₂C₆H₄OH (0.67%C₆H₅OH) K₃S=89.14, H=7.25, O=3.60; Found: C=88.86, H=7.53, O=3.74, Br=0.00. Functional yield =100%.

Preparation of PS-SiMe₃

Highly reactive calcium (1.93 mmol) was added to a solution containing p-bromopolystyrene (0.48 mmol Br) in THF (30 mL) at room temperature and stirred for 48 hours. Chlorotrimethylsilane (25.47 mmol) was added neat via a syringe and stirred for 24 hours at room temperature. Isolation and purification yielded 0.1048 g of a yellow-beige powder. FTIR: observed peaks at 1247 and 756 cm⁻¹ for the Si—C bonds. Anal. calcd. for (C₆H₅O)₂C₆H₄O(C₆H₄O)₃Si=5.26; Found: Si=5.08. Functional yield =43%.

Preparation of PS-CH₂C₆Br

Highly reactive calcium (3.20 mmol) was added to a solution containing p-bromopolystyrene (1.26 mmol Br) in THF (30 mL) and stirred for 48 hours at room tem-
The addition of highly reactive calcium species to 1% cross-linked chloromethylated polystyrene to generate the benzylic calcium-substituted reagent occurred with complete loss of chlorine after 6 hours at 0°C. Addition of CO₂(g) at -45°C followed by hydrolysis gave the carboxylated product (Table III, entry 3) in 93% functional yield. The functional yield of the carboxylated polymer was based on acid-base titration. The FTIR spectrum of the product confirmed the absence of the CH₂Cl precursor at 1266 cm⁻¹ and the presence of the carboxyl group at 1711 cm⁻¹.

The calcium-substituted reagent reacted with cyclohexanone and benzaldehyde in Grignard-type chemistry and quantitatively yielded the tertiary and secondary alcohols, respectively (Table III, entries 5 and 6). The addition of chlorodiphenylphosphine to the calcium-substituted reagent, prepared from the more functionalized polymer (5.50 mmol Cl/g, DF = 0.80, 2% DVB cross-linking), afforded the phosphine-containing polymer in 40% yield (Table III, entry 7).

The chemical reactivity of the benzylic calcium-substituted reagent was further explored with an epoxide-opening reaction. The addition of 1,2-epoxycyclohexene afforded the secondary alcohol (Table III, entry 8). The FTIR spectrum of the alcohol yielded a broad OH stretch around 3400 cm⁻¹ with a sharp peak at 3643 cm⁻¹ for the “free” OH stretch. The unbonded or “free” hydroxyl group of alcohols and phenols absorbs strongly in the 3650-3584 cm⁻¹ region, as evidenced by R. M. Silverstein et al., *Spectrometric Identification of Organic Compounds*, Wiley and Sons: New York, Fourth edition (1981). This may be due to the site isolation of the alcohol within the polymer and therefore no intermolecular hydrogen bonding. This is in agreement with that found when the secondary alcohol was formed using benzaldehyde (Table III, entry 6).

Preformed lithium anthracenide was reacted with calcium iodide to prepare a soluble calcium species. This calcium species was added to chloromethylated polystyrene (DF = 0.11) and stirred for 24 hours at room temperature. The corresponding calcium-substituted reagent was then reacted with chlorotrimethylsilane at room temperature to yield the silylated product; however, the yield was not optimized and was lower than the yield obtained from preformed lithium biphenylide (Table III, entry 4). Reaction of the calcium species with chloromethylated polystyrene at 0°C for 6 hours resulted in a 100% loss of chlorine from the polymer. Subsequent reaction with benzaldehyde gave the corresponding secondary alcohol in 80% yield, compared to the 100% yield when calcium biphenylide was used (Table III, entry 6).

*Chloromethylated polystyrene, 1.06 mmol Cl/g, DF = 0.11, 1% DVB cross-linking.

Preparation of PS-CH₃

Highly reactive calcium (0.90 mmol) was added to a solution containing chloromethylated polystyrene (0.59 mmol Cl, based on 1.06 mmol Cl/g, DF = 0.11, 1% DVB cross-linking) in THF (30 mL) and stirred at 0°C for 6 hours. The polymer was filtered and yielded a red-brick colored solid. Fresh THF (30 mL) was added to the polymer followed by the addition of deionized water (20 mL) and stirred for 24 hours at room temperature. Isolation of the product yielded 0.4495 g of an off-white powder. FTIR: absence of peak at 1266 cm⁻¹ for chlorinated precursor. Anal. Found: Cl = 0.00.

Preparation of PS-CH₂D

Highly reactive calcium (11.34 mmol) was added to a solution containing chloromethylated polystyrene (2.82 mmol Cl, based on 5.50 mmol Cl/g, DF = 0.80, 2% DVB cross-linking) in THF (30 mL) and stirred for 96 hours at room temperature. Deuterium oxide (10 mL) was added and stirred for 48 hours at room temperature. Isolation of the product yielded 1.0622 g of a gray powder. FTIR: observed peak at 2260 cm⁻¹ for C-D bond. HR EI-MS yielded fragments at 119.0847 m/e for C₃H₃D⁺ (4.11%), at 92.0615 m/e for C₃H₃D⁺ (9.49%), at 130.0768 m/e for C₅H₅D⁺ (1.58%), 118.0770 m/e for C₅H₅D⁺ (2.39%), and at 104.0617 m/e for C₆H₆⁺ (2.51%). Anal. Found: Cl = 0.27 (99% loss).

Preparation of PS-CH₂COOH

Highly reactive calcium (1.15 mmol) was transferred to a solution containing chloromethylated polystyrene (0.71 mmol Cl, based on 1.06 mmol Cl/g) in THF (30 mL) and stirred for 6 hours at 0°C. The polymer was filtered and fresh THF (30 mL) was added. Gaseous carbon dioxide was passed through a Drierite™ column and bubbled into the reaction flask at 45°C for 2 hours, and at 0°C for 1 hour. The reaction mixture was hydrolyzed with 1:1 H₂O/0.5 N HCl (20 mL). The solution was stirred for 1 hour at 0°C and warmed to room temperature for 12 hours. Isolation of the product yielded 0.4836 g of an off-white powder. FTIR: observed peak at 1711 cm⁻¹ for the carboxyl group. Acid-based titrations yielded 0.99 mmol COOH/g or 93% functional yield. Anal. Found: Cl = 0.00.
Preparation of PS-CH$_2$SiMe$_3$

Highly reactive calcium (1.50 mmol) was added to a solution containing chloromethylated polystyrene (0.61 mmol Cl, based on 1.06 mmol Cl/g) in THF (30 mL) and stirred for 40 hours at room temperature. Chlorotrimethyloxysilane (3.05 mmol) in THF (30 mL) was added and stirred at room temperature for 48 hours. Isolation of the product yielded 0.5503 g of a white powder. FTIR: observed peaks at 1248 and 755 cm$^{-1}$ for the Si–C bond. Anal. calcd. for (C$_{9}$H$_{10}$)$_{0.01}$(C$_{6}$H$_{5}$)$_{0.05}$(CH$_{3}$)$_{2}$SiH$_{1.8}$: C=89.97, H=8.01, Si =2.01; Found: C=90.02, H=7.80, Si=1.75, Cl=0.00. Functional yield = 75%.

Preparation of PS-CH$_2$COHCH$_3$

Highly reactive calcium (1.27 mmol) was added to a solution containing chloromethylated polystyrene (0.84 mmol Cl, based on 1.06 mmol Cl/g) in THF (30 mL) and stirred for 6 hours at 0°C. The polymer was filtered and fresh THF (30 mL) was added. Cyclohexanone (2.24 mmol in THF (10 mL) was added at −45°C and stirred for 1 hour at −45°C. The mixture was allowed to warm to room temperature with stirring over a period of 16 hours. To this mixture, H$_2$O (50 mL) was added. The mixture was stirred for 1 hour at room temperature. Isolation of the product yielded 0.7246 g of a white powder. FTIR: observed sharp peak at 3573 cm$^{-1}$ for “free” OH stretch, broad peak around 3460 cm$^{-1}$ for OH stretch and at 1030 cm$^{-1}$ for the C–O stretch. Anal. calcd. for (C$_{9}$H$_{10}$)$_{0.01}$(C$_{6}$H$_{5}$)$_{0.05}$ (C$_{3}$H$_{5}$O)$_{0.11}$, L=90.43, H=8.04, O=1.51; Found: C=90.18, H=7.89 O=1.66, Cl=0.00. Functional yield = 100%.

Preparation of PS-CH$_2$CH(OH)CH$_3$

Highly reactive calcium (1.49 mmol) was added to a solution containing chloromethylated polystyrene (0.98 mmol Cl, based on 1.06 mmol Cl/g) in THF (30 mL) and stirred for 6 hours at 0°C. The polymer was filtered and fresh THF (30 mL) was added. Benzaldehyde (4.26 mmol) in THF (10 mL) was added at −45°C and stirred for 1 hour. The mixture was allowed to warm to room temperature with stirring over a period of 16 hours. At this time, H$_2$O (20 mL) was added and stirred for 1 hour at room temperature. Isolation of the product yielded 0.890 g of a yellow-white powder. FTIR: observed sharp peak at 3642 cm$^{-1}$ for “free” OH stretch, broad peak around 3550-3600 cm$^{-1}$ for the OH stretch and at 1026 cm$^{-1}$ for the C–O stretch. Anal. calcd. for (C$_{9}$H$_{10}$)$_{0.01}$(C$_{6}$H$_{5}$)$_{0.05}$(C$_{3}$H$_{5}$O)$_{0.11}$, C=90.97, H=7.62, O=1.49; Found: C=91.04, H=7.58, O=1.86, Cl=0.00. Functional yield = 100%.

Preparation of PS-CH$_2$PPH$_2$

Highly reactive calcium was added to a solution containing chloromethylated polystyrene (1.51 mmol Cl, based on 5.50 mmol Cl/g, DF=0.80) in THF (30 mL) and stirred for 48 hours at room temperature. Chlorodiphenylyphosphine (6.03 mmol) in THF (10 mL) was added at 0°C. The mixture was stirred for 1 hour, and then allowed to warm with stirring to room temperature over a period of 48 hours. Added 3:1 acetone/H$_2$O (20 mL) and stirred for 1 hour at room temperature. Isolation of the product yielded 0.2000 g of a light yellow powder. FTIR: observed weak peaks at 1001, 1452 and 1492 cm$^{-1}$ for P–Ar bonds. Anal. calcd. for (C$_{9}$H$_{10}$)$_{0.02}$(C$_{6}$H$_{5}$)$_{0.18}$(C$_{6}$H$_{5}$)$_{0.00}$ (C$_{3}$H$_{5}$P)$_{0.52}$.

Preparation of PS-CH$_2$C$_6$H$_5$(OH)

Highly reactive calcium (1.81 mmol) was added to a solution containing chloromethylated polystyrene (1.19 mmol Cl, based on 1.06 mmol Cl/g) in THF (30 mL) and stirred for 6 hours at 0°C. The polymer was filtered and fresh THF (30 mL) was added. 1,2-Epoxydicyclopentene (4.75 mmol) in THF (10 mL) was added at −45°C, and the mixture was stirred for 2 hours at −45°C. It was allowed to warm with stirring to room temperature over a period of 48 hours. To this polymer mixture, H$_2$O (20 mL) was added. It was then stirred for 1 hour at room temperature. Isolation of the product yielded 0.9282 g of an off-white powder. FTIR: observed sharp peak at 3643 cm$^{-1}$ for “free” OH stretch, broad peak around 3400 cm$^{-1}$ for OH stretch and at 1028 cm for C–O stretch.

EXAMPLE 5

Preparation of Insoluble Calcium-Substituted Polymeric Reagents From p-Fluoroplstyrene and p-Chloroplstyrene and Reactions Thereof

Significantly, the highly reactive calcium species produced according to the method of Example 1 will undergo oxidative addition with 3% cross-linked p-fluoroplstyrene and p-chloroplstyrene to prepare the corresponding calcium-substituted reagents with 100% loss of the halogen after 80 hours at room temperature. The addition of the calcium species to p-fluoroplstyrene and stirring for 48 hours at room temperature resulted in a 71% loss of the directly bonded fluorine. After reacting 48 hours at room temperature, 81% of the directly bonded chlorine was lost from the starting p-chloroplstyrene polymer.

The polymeric calcium-substituted reagent produced from p-fluoroplstyrene was found to react with chlorotrimethyloxysilane which gave the silylated polymer in a 26% yield (Table V, entry 3). The reaction was stirred for 1 hour at 0°C and then 16 hours at room temperature. The addition of benzaldehyde to the polymeric calcium-substituted reagent, produced from p-fluoroplstyrene, and subsequent reaction for 96 hours yielded the secondary alcohol in 25% functional yield (Table V, entry 7).

The polymeric calcium-substituted reagent formed from p-chloroplstyrene reacted with chlorotrimethyloxysilane and gave the functionalized polymer in a 13% yield (Table IV, entry 3). The reaction was stirred for 48 hours at room temperature. The addition of benzaldehyde and subsequent reaction for 96 hours at room temperature gave the secondary alcohol in 16% yield (Table IV, entry 6).

Polymers containing fluorine and chlorine with 1% or 2% cross-linking and lower loadings were not prepared but are expected to produce higher functional yields of the resulting polymers with shorter reaction times.

Preparation of Functionalized Polymer PS-COOH

From p-fluoropolystyrene: Highly reactive calcium (3.48 mmol) was added to a solution containing p-fluoropolystyrene (1.38 mmol F, based on 2.59 mmol F/g) in THF (30 mL) and stirred for 96 hours at room temperature. Gaseous carbon dioxide was passed through a column of Drierite TM and bubbled into the solution at −45°C for 2 hours, at 0°C for 1 hour, and at room temperature for 1 hour. To this reaction mixture, more was added 0.5N HCl (15 mL). This was stirred for 30 minutes at room temperature. The polymer was then filtered. Filtered polymer was washed with 0.5N HCl, THF, and MeOH. Drying yielded 0.1474 g of a light gray powder. FTIR: observed peak at 1746 cm⁻¹ for the carboxyl group and disappearance of aryl fluoride at 1230 cm⁻¹. Aryl fluoride absorptions in the 1250-1210 cm⁻¹ region and monofluorinated benzenes display a strong absorption band near 1230 cm⁻¹. See R.M. Silverstein et al., Spectrometric Identification of Organic Compounds, Wiley and Sons: New York, 1981, Fourth edition. Acid-base titrations yielded 2.02 mmol 50% COOH g or 78% functional yield. Anal. Found: F = 0.00.

From p-chloropolystyrene: Highly reactive calcium (3.72 mmol) was added to a solution containing p-chloropolystyrene (1.46 mmol Cl, based on 3.75 mmol Cl/g) in THF (30 mL) and stirred for 96 hours at room temperature. Gaseous carbon dioxide was passed through a column of Drierite TM and bubbled into the solution at −45°C for 2 hours, at 0°C for 1 hour, and at room temperature for 1 hour. To this was added 1.0N HCl (20 mL). The mixture was stirred for 30 minutes at room temperature. Isolation of the product yielded 0.3002 g of a light gray powder. FTIR: observed peak at 1742 cm⁻¹ for the carboxyl group and the disappearance of aryl chloride at 1090 cm⁻¹. Chloroarenes absorb in the 1096-1089 cm⁻¹ region. See R.M. Silverstein et al., Spectrometric Identification of Organic Compounds, Wiley and Sons: New York, 1981, Fourth edition. Acid-base titrations yielded 3.07 mmol COOH g or 82% functional yield. Anal. Found: Cl = 0.00.

Preparation of Functionalized Polymer PS-SiMe₃

From p-fluoropolystyrene: Highly reactive calcium (3.08 mmol) was added to a solution containing p-fluoropolystyrene (2.05 mmol F) in THF (30 mL) and stirred for 120 hours at room temperature. The polymer was filtered, fresh THF (30 mL) added, and the mixture was cooled to 0°C. Chlorotrimethylsilane (4.32 mmol) in THF (10 mL) was added at 0°C and stirred for 1 hour. The mixture was allowed to warm from 0°C with stirring to room temperature over a period of 16 hours. Isolation of the product yielded 1.3461 g of a white powder. FTIR: observed peaks at 1249 and 756 cm⁻¹ for the Si-C bonds. Anal. calc. for C₆H₅O₃SiMe₃: 0.87% C₆H₅O₃SiMe₃; Si = 1.86; Found: Si = 1.66. Functional yield = 26%.

From p-chloropolystyrene: Highly reactive calcium (2.80 mmol) was added to a solution containing p-chloropolystyrene (1.89 mmol Cl) in THF (30 mL) and stirred for 96 hours at room temperature. The polymer was filtered, fresh THF (30 mL) added, and the mixture was cooled to −78°C. Chlorotrimethylsilane (6.94 mmol) in THF (10 mL) was added at −78°C, and the mixture was stirred at −78°C for 2 hours. It was allowed to warm with stirring to room temperature over a period of 48 hours. Isolation of the product yielded 0.4517 g of a yellow-white powder. FTIR: observed peaks at 1250 and 756 cm⁻¹ for Si-C bonds. Anal. calc. for C₆H₅O₃SiMe₃: 0.87% C₆H₅O₃SiMe₃; Si = 1.50; Found: Si = 1.22. Functional yield = 13%.

Preparation of Functionalized Polymer PS-PPh₂

From p-fluoropolystyrene: Highly reactive calcium (1.95 mmol) was added to a solution containing p-fluoropolystyrene (1.31 mmol P) in THF (30 mL) at −78°C. The mixture was stirred for 1 hour at −78°C, and then allowed to warm to room temperature over a period of 90 hours. The polymer was filtered, fresh THF (30 mL) added, and the mixture was cooled to −78°C. Chlorodiphenylphosphine (4.10 mmol) in THF (10 mL) was added at −78°C and stirred for 1 hour. The mixture was then allowed to warm with stirring to room temperature over a period of 48 hours. Isolation of the product yielded 0.4788 g of a light yellow powder. FTIR: observed peaks at 1003 and 1492 cm⁻¹ for P-Ar bonds. Anal. calc. for C₆H₄O₂P(C₆H₅)₂: 0.31% C₆H₄O₂P(C₆H₅)₂; P = 0.87; Found: 0.60. Functional yield = 11%.

Preparation of Functionalized Polymer PS-CH(OH)C₆H₅

From p-fluoropolystyrene: Highly reactive calcium (2.61 mmol) was added to a solution containing p-fluoropolystyrene (1.71 mmol F) in THF (30 mL) at −45°C and stirred for 4 hours. The mixture was allowed to warm with stirring to room temperature over a period of 96 hours. The polymer was filtered, fresh THF (30 mL) was added, and the mixture was cooled to −45°C. Benzaldehyde (4.59 mmol) in THF (10 mL) was added at −45°C. The mixture was stirred for 4 hours at −45°C, and then allowed to warm to room temperature over a period of 96 hours. Deionized H₂O (20 mL) was added at room temperature and stirred for 24 hours. Isolation of the product yielded 0.3415 g of a yellowish-white powder. FTIR: observed sharp peak at
Preparation of Functionalized Polymer PS-COCH₃

From p-fluoropolystryrene: Highly reactive calcium (1.72 mmol) was added to a solution containing p-fluoropolystryrene (1.13 mmol Cl) in THF (30 mL) at −78° C. The mixture was then stirred for 1 hour at −78° C, and allowed to warm to room temperature over a period of 80 hours. The polymer was filtered, fresh THF (30 mL) was added, and the reaction mixture was cooled to −45° C. To this mixture, CuCN (1.49 mmol) and LiBr (3.12 mmol) in THF (10 mL) were added. The entire mixture was stirred for 4 hours at −45° C. Acetyl chloride (6.49 mmol) in THF (10 mL) was then added at −45° C with additional stirring for 4 hours. The mixture was allowed to warm from −45° C to room temperature. It was then stirred for an additional 48 hours. Isolation of the product yielded 0.2949 g of a light gray powder. FTIR: observed a peak at 1685 cm⁻¹ for the carbonyl. Anal. calc. for \( \text{C}_9\text{H}_{10}\text{O}_2\text{Cl} \): C=90.08, H=7.56, O=2.35; Found: C=90.14, H=7.53, O=2.27. Functional yield = 59%.

From p-chloropolystryrene: Highly reactive calcium (2.18 mmol) was added to a solution containing p-chloropolystryrene (1.43 mmol Cl) in THF (30 mL) at −78° C and stirred for 1 hour. The mixture was allowed to warm from −78° C to room temperature with stirring over a period of 80 hours. The polymer was filtered, fresh THF (30 mL) was added, and the mixture was cooled to −45° C. CuCN (1.52 mmol) and LiBr (3.14 mmol) in THF (10 mL) were added to this mixture at −45° C, and stirred for an additional 4 hours. Acetyl chloride (4.40 mmol) in THF (10 mL) was added at −45° C and stirred for 4 hours. The mixture was then warmed from −45° C to room temperature with stirring over a period of 48 hours. Isolation of the product yielded 0.1723 g of a light grey powder. FTIR: observed peak at 1682 cm⁻¹ for the carbonyl. Anal. calc. for \( \text{C}_9\text{H}_{10}\text{O}_2\text{Cl} \): C=90.57, H=7.60, O=1.83; Found: C=88.55, H=7.56, O=1.60. Functional yield = 28%.

EXAMPLE 6

Preparation and Reactions of Calcium-Substituted Polymeric Cuprate Reagents From p-Bromopolystryrene

Addition of a copper(I) salt to the calcium-substituted reagent resulted in a new reagent of vastly different chemical reactivity. Table VI and Table VII present some of the reactions of the calcium-substituted polymeric cuprate reagents with various electrophiles. A soluble copper(I) complex, CuCN-2LiBr was used for the reactions with the calcium-substituted reagents to prepare the copper calcium reagents. The CuCN-2LiBr can be prepared from CuCN and LiBr in THF, as outlined in P. Kocienski et al., J. Org. Chem., 53, 2390 (1988), which is incorporated herein by reference. Reaction of the calcium-substituted polymeric reagent, after removal of excess highly reactive calcium, with 1.05–1.10 equivalents of CuCN-2LiBr (based on starting halide) proceeded at −45° C for 2 hours. The calcium-substituted cuprate formed from p-bromopolystryrene (DF = 0.31) was reacted with benzoyl chloride at −45° C with warming to room temperature. This afforded the ketone-containing polymer (Table VI, entry 1) in a 90% functional yield as evidenced by elemental analyses. FTIR, high resolution EI-MS, and elemental analy-
The reaction of the calcium-substituted reagent and benzoyl chloride and acetyl chloride was used to characterize the polymer. Reaction of the calcium-substituted reagent with benzoyl chloride and no reaction with CuCN-LiBr also resulted in a 70% yield of the ketone product.

The reaction of acetyl chloride with the calcium cuprate reagent gave the ketone-containing polymer (Table VI, entry 3) in a quantitative yield. When the reaction was carried out in one pot without filtration of the excess highly reactive calcium and 0.74 equivalents of CuCN-LiBr, the ketone product was formed in a 76% yield.

The reaction of the calcium cuprate reagent with a functionalized alkyl halide, ethyl 4-bromobutyrate, gave the ester functionalized polymer (Table VI, entry 5) in a 60% yield. Without reaction with CuCN-LiBr, the product was formed in only 40% with 5% of the bromine-containing polymer found.

In addition, the calcium cuprate reagents undergo conjugate 1,4-addition with α,β-unsaturated ketones. Reaction of the calcium cuprate reagent with 2-cyclohexen-l-one afforded the conjugate addition product in 90% yield (Table VI, entry 6). The FTIR spectrum of the product showed the presence of a strong peak in the 1705-11 cm⁻¹ region for the carbonyl and the absorption of the aryl bromide precursor at 1408, 1072, 1010, and 718 cm⁻¹. The same reaction was carried out with filtration of the polymer after the formation of the calcium cuprate, and 2-cyclohexen-l-one was added. This gave the ketone product in 45% functional yield.

*Reaction with CuCN-LiBr.*

Highly reactive calcium (1.95 mmol) was added to a solution containing p-bromostyrene (1.29 mmol Br) based on 2.44 mmol Br/g, DF = 0.31, 3% DVB cross-linking.

Preparation of PS-COClC₆H₄ Using CuCN-LiBr

Highly reactive calcium (1.95 mmol) was added to a solution containing p-bromostyrene (1.29 mmol Br) in THF (30 mL) and stirred for 36 hours at room temperature. The polymer was filtered and fresh THF (30 mL) was added and cooled to −45°C. CuCN (1.40 mmol) and LiBr (3.09 mmol) in THF (10 mL) were pre-cooled to −45°C and added to the polymer solution. The polymer was stirred for 2 hours at −45°C. At which time benzoyl chloride (4.94 mmol) in THF (10 mL) was added and stirred for 1 hour at −45°C with warming to room temperature over a period of 48 hours. Insoylation of the product yielded 0.3916 g of a tan powder. FTIR: peak observed at 1663 cm⁻¹ for the carbonyl and the absence of peaks at 1408, 1072, 1010, and 718 cm⁻¹ for the aryl bromide precursor. HR EI-MS yield fragments at 105.0341 m/e for C₆H₅O⁺ (21.65%), 130.0783 m/e for C₅H₁₀H⁺ (3.48%), and at 104.0623 m/e for C₅H₄⁺ (100%). Anal. calcd. for (C₆H₁₀H)₂O,C₆H₅O⁻, C=89.76, H=6.90, O=3.33; Found: C=89.84, H=7.46, O=3.24, Br=0.00. Functional yield = 90%.

Preparation of PS-COClC₆H₄(p-Cl) Using CuCN-LiBr

Highly reactive calcium (3.60 mmol) was added to a solution containing p-bromostyrene (1.39 mmol Br) in THF (30 mL) and stirred for 48 hours at room temperature. CuCN (2.62 mmol) and LiBr (4.86 mmol) in THF (10 mL) were pre-cooled to −45°C, added to the polymer solution, and stirred for 2 hours at −45°C. CuCN-LiBr (3.15 mmol) was added and stirred for 2 hours at −45°C. 4-Chlorobenzoyl chloride (7.15 mmol) in THF (10 mL) was added and stirred for 2 hours at −45°C with warming to room temperature over a period of 41 hours. Isolation of the product yielded 0.5405 g of a light tan powder. FTIR: observed peak at 1660 cm⁻¹ for carbonyl and at 1090 cm⁻¹ for the aryl chloride. Anal. calcd. for (C₁₀H₁₀O₂)(C₆H₄O₂)(C₅H₅O)(C₅H₄O).Cl, C=34.5; Found: C=33.6; Br=0.00. Functional yield = 38%.

Preparation of PS-COClC₆H₄ Using CuCN-LiBr

Highly reactive calcium (2.04 mmol) was added to a solution containing p-bromostyrene (1.34 mmol Br) in THF (30 mL) and stirred for 36 hours at room temperature. The polymer was filtered, fresh THF (30 mL) was added, and the mixture was cooled to −45°C. CuCN (1.58 mmol) and LiBr (3.28 mmol) in THF (10 mL) were pre-cooled to −45°C and added to the polymer. The polymer was stirred for 2 hours at −45°C, at which time acetyl chloride (4.70 mmol) in THF (10 mL) was added and stirred for 1 hour at −45°C with warming to room temperature over a period of 48 hours. Isolation of the product yielded 0.3516 g of a tan powder. FTIR: observed peak at 1686 cm⁻¹ for the carbonyl. Anal. calcd. for (C₁₀H₁₀O₂)(C₆H₄O₂)(C₅H₅O)(C₅H₄O).Cl, C=88.37, H=7.41, O=4.21; Found: C=88.54, H=7.79, O=4.33, Br=0.00. Functional yield = 100%.

Preparation of PS-(CH₂)₃CN Using CuCN-LiBr

Highly reactive calcium (1.95 mmol) was added to a solution containing p-bromostyrene (1.29 mmol Br) in THF (30 mL) and stirred for 48 hours at room temperature. The polymer was filtered, fresh THF (30 mL) was added, and the mixture was cooled to −45°C. CuCN (1.51 mmol) and LiBr (3.38 mmol) in THF (10 mL) were pre-cooled to −45°C, added to the polymer and stirred for 2 hours at −45°C, 4-Bromo-butyronitrile (4.05 mmol) in THF (10 mL) was added at −45°C, stirred for 1 hour at −45°C with warming to room temperature over a period of 48 hours. Isolation of the product yielded 0.2957 g of a yellow-tan powder. FTIR: observed peak at 2247 cm⁻¹ for the nitrile. Anal. calcd. for (C₁₀H₁₀O₂)(C₆H₄O₂)(C₅H₅O)(C₅H₄O).N, C=84.91; Found: N=0.80, Br=0.00. Functional yield = 23%.

Preparation of S-(CH₂)₂COEt Using CuCN-LiBr

Highly reactive calcium (2.96 mmol) was added to a solution containing p-bromostyrene (1.18 mmol Br) in THF (30 mL) and stirred for 48 hours at room temperature. The solution was cooled to −45°C at which time CuCN (1.91 mmol) and LiBr (4.04 mmol) in THF (10 mL) were added and stirred for 2 hours at −45°C. Ethyl 4-bromobutyrate (6.34 mmol) in THF (10 mL) was added at −45°C, stirred for 2 hours at −45°C and warmed to room temperature over a period of 68 hours. Isolation of the product yielded 0.3701 g of a tan powder. FTIR: peak observed at 1736 cm⁻¹ for the ester carbonyl and at 1183 cm⁻¹ for the C=O stretch. Anal. calcd. for (C₁₀H₁₀O₂)(C₆H₄O₂)(C₅H₅O)(C₅H₄O).S, C=87.34, H=7.92, O=4.73; Found: C=87.73, H=7.45, O=4.88, Br=0.00. Functional yield = 60%.
Preparation of PS-C6H5O Using CuCN-2LiBr

Highly reactive calcium (1.32 mmol) was added to a solution containing p-bromopolystyrene (0.90 mmol Br) in THF (30 mL) and stirred for 48 hours at room temperature. The polymer was filtered, fresh THF (30 mL) was added, and the mixture was cooled to -45°C. CuCN (1.42 mmol) and LiBr (2.80 mmol) in THF (10 mL) were added at -45°C and stirred for 2 hours at -45°C. Cyclicosken-1-one (2.50 mmol) in THF (10 mL) was added at -45°C and stirred for 2 hours at -45°C with warming to room temperature over a period of 24 hours. The polymer was quenched with 3N HCl (8 mL) and stirred for 20 minutes. Isolation of the product yielded 0.3059 g of a tan powder. FTIR: observed a peak at 1709 cm⁻¹ for the carbonyl. Anal. calcd. for (C10H10)0.001(C8H8)0.881(C9H10)0.0069,(C3H15N)0.0041, N=0.52; Found: N=0.50, Cl=0.00. Functional yield=90%.

EXAMPLE 7
Preparation and Reactions of Calcium-Substituted Polymeric Cuprate Reagents From Chloromethylated Polystyrene

The calcium-substituted reagent prepared from highly reactive calcium and chloromethylated polystyrene (DF=0.11) was also reacted with CuCN-2LiBr at -45°C. For 2 hours to generate the benzylic calcium cuprate reagent. Addition of benzyl chloride at -45°C with warming to room temperature yielded the keto-containing polymer in a quantitative yield (Table VII, entry 1). Without reaction with CuCN-2LiBr, only a 60% yield of the ketone polymer was obtained. The calcium cuprate formed from the higher functionalized chloromethylated polystyrene (5.50 mmol Cl/g, DF=0.80, 2% DVB cross-linking) was reacted with benzyl chloride and afforded the ketone product in a 61% yield. Reaction of the calcium-substituted reagent from chloromethylated polystyrene, which was stored for 1 month under inert atmosphere conditions at room temperature, with CuCN-2LiBr followed by reaction with benzyl chloride afforded the ketone product in a 95% yield.

As with p-bromopolystyrene, this new chemical reactivity of the calcium cuprate reagent with 2-cyclohexen-1-one afforded the conjugate addition product in a quantitative yield (Table VII, entry 5). The FTIR spectrum of the product yielded an intense peak for the carbonyl in the 1709-11 cm⁻¹ region with loss of the chloromethyl peak at 1266 cm⁻¹.

The calcium-substituted reagents formed from p-chloropolystyrene and p-fluoropolystyrene underwent reaction with CuCN-2LiBr at -45°C. For 4 hours to prepare the calcium cuprate reagent. Addition of acetyl chloride afforded the ketone products in 28% and 59% yields, respectively (Table IV, entry 5 and Table V, entry 6). The FTIR spectra showed the presence of a strong peak around 1682-85 cm⁻¹ for the carbonyl of both polymers and the absence of the aryl fluoride and chloride precursors at 1230 and 1090 cm⁻¹, respectively.

Preparation of PS-CH2COCH3 Using CuCN-2LiBr

Highly reactive calcium (1.44 mmol) was added to a solution containing chloromethylated polystyrene (0.58 mmol Cl, based on 1.06 mmol Cl/g, DF=0.11) in THF (30 mL) and stirred at room temperature for 40 hours. CuCN (0.86 mmol) and LiBr (1.69 mmol) in THF (10 mL) were added at -42°C and stirred for 2 hours at -42°C. Benzyl chloride (2.26 mmol in THF (10 mL) was added at -42°C, stirred for 2 hours at -42°C and warmed to room temperature over a period of 48 hours. Isolation of the product yielded 0.5125 g of a light gray powder. FTIR: observed a peak at 1682 cm⁻¹ for the carbonyl and disappearance of the chloride precursor at 1266 cm⁻¹. Anal. calcd. for (CH3)2OCH2(C6H5)0.88(C6H5)0.11, C=91.05, H=7.45, O=1.50; Found: C=91.40, H=7.29, O=1.18, Cl=0.00. Functional yield=100%.

Preparation of PS-CH2COCH3 Using CuCN-2LiBr

Highly reactive calcium (0.97 mmol) was added to a solution containing chloromethylated polystyrene (0.65 mmol Cl) in THF (30 mL) and stirred for 6 hours at 0°C. The polymer was filtered, fresh THF (30 mL) was added, and the mixture was cooled to -45°C. CuCN (0.85 mmol) and LiBr (1.59 mmol) in THF (10 mL) were added at -45°C. The mixture was stirred for 2 hours at -45°C. Acetyl chloride (2.53 mmol) in THF (10 mL) was added at -45°C, stirred for 1 hour at -45°C, and warmed to room temperature for 18 hours. Isolation of the product yielded 0.5809 g of a light gray powder. FTIR: observed a peak at 1713 cm⁻¹ for the carbonyl. Anal. calcd. for (CH3)2OCH2(C6H5)0.88(C6H5)0.11, C=90.70, H=7.80, O=1.59; Found: C=90.85, H=7.77, O=1.94, Cl=0.00. Functional yield=100%.

Preparation of PS-(CH2)3 Using CuCN-2LiBr

Highly reactive calcium (0.97 mmol) was added to a solution containing chloromethylated polystyrene (0.61 mmol Cl) in THF (30 mL) and stirred for 6 hours at 0°C. The polymer was filtered, fresh THF (30 mL) was added, and the mixture was cooled to -45°C. CuCN (1.04 mmol) and LiBr (2.37 mmol) in THF (10 mL) were added at -45°C. The mixture was stirred for 2 hours at -45°C. 4-Bromobutyronitrile (1.65 mmol) in THF (10 mL) was added at -45°C, stirred for 1 hour at -45°C, and the mixture was warmed to room temperature over a period of 18 hours. Isolation of the product yielded 0.2650 g of a dark powder. FTIR: observed a peak at 2250 cm⁻¹ for the nitrile. Anal. calcd. for (CH3)2OCH2(C6H5)0.88(C6H5)0.11, C=31.84, H=5.11, N=0.04; Found: N=0.52. Functional yield=37%.

Preparation of PS-(CH_2)_nCO_2Et Using CuCN_2LiBr

Highly reactive calcium (0.93 mmol) was added to a solution containing chloromethylated polystyrene (0.60 mmol Cl) in THF (30 mL) and stirred for 6 hours at 0°C. The polymer was filtered, fresh THF (30 mL) was added, and the mixture was cooled to -45°C. CuCN (0.99 mmol) and LiBr (2.29 mmol) in THF (10 mL) were added at -45°C and stirred for 2 hours at -45°C. Ethyl 4-bromobutyrate (1.61 mmol) in THF (10 mL) was added at -45°C. The mixture was stirred for 2 hours at -45°C, and then warmed to room temperature with stirring over a period of 18 hours. Isolation of the product yielded 0.4072 g of a yellow powder. FTIR: observed a peak at 1742 cm\(^{-1}\) for the ester carbonyl and at 1184 cm\(^{-1}\) for the C-O stretch. Anal. calcd. for (C\(_{10}\)H\(_9\)O\(_3\))\(_2\)(C\(_{14}\)H\(_{18}\)O\(_2\))\(_{0.02}\)C\(_{2}\)H\(_2\)O\(_2\)C\(_{12}\)H\(_{16}\)O\(_{2}\): C = 89.64, H = 7.90, O = 2.43; Found: C = 89.15, H = 7.70, O = 2.39, Cl = 0.00. Functional yield = 80%.

Preparation of PS-CH\(_2\)C\(_6\)H\(_4\)O Using CuCN_2LiBr

Highly reactive calcium (0.84 mmol) was added to a solution containing chloromethylated polystyrene (0.55 mmol Cl) in THF (30 mL) at 0°C for 6 hours. The polymer was filtered, fresh THF (30 mL) was added, and the mixture was cooled to -45°C. CuCN (0.88 mmol) and LiBr (1.88 mmol) in THF (10 mL) were added at -45°C, and the mixture was stirred for 2 hours at -45°C. 2-Cyclohexenyl-1-one (1.55 mmol) in THF (10 mL) was added at -45°C and stirred for 2 hours with warming to room temperature over a period of 24 hours. The polymer was quenched with 3 N HCl (8 mL) and stirred for 20 minutes. Isolation of the product yielded 0.4716 g of a light brown powder. FTIR: observed peak at 1709 cm\(^{-1}\) for the carbonyl. Anal. calcd. for (C\(_{10}\)H\(_9\)O\(_2\))(C\(_{15}\)H\(_{18}\)O\(_2\))\(_{0.11}\)C = 90.69, H = 7.80, O = 1.51; Found: C = 90.44, H = 7.87, O = 1.33, Cl = 0.00. Functional Yield = 100%.

**EXAMPLE 8**

Preparation of Bifunctional polymers Utilizing Highly Reactive Calcium

The addition of highly reactive calcium to a chlorine-containing polymer, previously functionalized by the electrophile p-CIC\(_6\)H\(_4\)COCI, and subsequent addition of chlorotrimethylsilane afforded the silylated product (Table VIII, entry 1) in a 60% yield. The FTIR spectrum of the polymer showed the presence of peaks at 1251 and 758 cm\(^{-1}\) for the Si-C bonds and at 1664 cm\(^{-1}\) for the carbonyl. Elemental analysis of the product confirmed the complete loss of the chlorine from the polymer. High resolution EI-MS yielded fragments at 73.0485 m/e for C\(_3\)H\(_4\)Si\(_2\), 181.0648 m/e for C\(_3\)H\(_3\)O\(^+\) and at 105.0337 m/e for C\(_3\)H\(_2\)O\(^+\). The addition of highly reactive calcium to a bromine-containing polymer and reaction with chlorotrimethylsilane gave the silylated product (Table VIII, entry 2) in 36% yield; however, this yield was not optimized.

*Elemental analyses.
*Based on 0.93 mmol Cl/g.
*Based on 0.77 mmol Br/g.

Preparation of PS-COC\(_6\)H\(_4\)SiMe\(_3\)

Highly reactive calcium (0.46 mmol) was added to a solution containing PS-\text{CO}C_{6}H_{4}(p-Cl) (0.14 mmol Cl), based on 0.93 mmol Cl/g) in THF (30 mL) at room temperature and stirred for 72 hours. Chlorotrimethylsilane (5.43 mmol) in THF (10 mL) was added at room temperature and stirred for 48 hours. To this was added 1:1 H\(_2\)O/5% HCl (25 mL). The mixture was stirred for 1 hour at room temperature. Isolation of the product yielded 0.0868 g of a tan powder. FTIR: observed peaks at 1251 and 755 cm\(^{-1}\) for the Si-Cl bonds and 1664 cm\(^{-1}\) for the carbonyl. Absence of aryl chloride precursor at 1030 cm\(^{-1}\). HR EI-MS yielded fragments at 73.0485 m/e for C\(_3\)H\(_2\)Si\(_3\) (8.14%), 105.0337 m/e for C\(_3\)H\(_2\)O\(^+\) (31.82%), 181.0648 for C\(_3\)H\(_2\)O\(^+\) (45.50%), and at 104.0626 m/e for C\(_3\)H\(_4\) (73.82%). Anal. calcd. for (C\(_{10}\)H\(_9\))\(_2\)(C\(_{14}\)H\(_{18}\))\(_{0.07}\)C\(_{15}\)H\(_{18}\)O\(_2\)Si\(_{0.07}\), Si = 1.63; Found: Si = 1.56, Cl = 0.00. Functional yield = 60%.

Preparation of PS-CH\(_2\)COC\(_6\)H\(_4\)SiMe\(_3\)

Highly reactive calcium (0.44 mmol) was added to a solution containing PS-CH\(_2\)COC\(_6\)H\(_4\)(p-Br) (0.09 mmol Cl/g, based on 0.77 mmol Br/g) in THF (30 mL) at room temperature and stirred for 48 hours at room temperature. Chlorotrimethylsilane (5.44 mmol) in THF (10 mL) was added, and the mixture was stirred at room temperature for 48 hours. Isolation of the product yielded 0.0929 g of a yellow-gray powder. FTIR: observed peaks at 1257 and 758 cm\(^{-1}\) for the Si-C bonds and 1687 cm\(^{-1}\) for the carbonyl. HR EI-MS yielded fragments at 73.0488 m/e for C\(_3\)H\(_2\)Si\(_3\) (5.96%), 105.0345 m/e for C\(_3\)H\(_2\)O\(^+\) (13.67%), at 178.0781 m/e for C\(_3\)H\(_4\)O\(^+\) (3.12%), at 130.0775 m/e for C\(_3\)H\(_2\)O\(^+\) (2.63%), and at 104.0625 m/e for C\(_3\)H\(_4\) (9.56%). Anal. calcd. for (C\(_{10}\)H\(_9\))\(_2\)(C\(_{14}\)H\(_{18}\))\(_{0.11}\)C\(_{15}\)H\(_{18}\)O\(_2\)Si\(_{0.07}\)C\(_{15}\)H\(_{18}\)Br\(_{0.07}\)C\(_{15}\)H\(_{18}\)O\(_2\)Si\(_{0.07}\), Si = 0.83; Found: Si = 0.77, Br = 3.03 (48% Br remaining). Functional yield = 36%.

Preparation of PS-COC\(_6\)H\(_4\)PPh\(_2\)

Highly reactive calcium (0.57 mmol) was added to a solution containing PS-\text{CO}C_{6}H_{4}(p-Cl) (0.18 mmol Cl), based on 0.93 mmol Cl/g) in THF (30 mL) at room temperature. The mixture was stirred for 72 hours at room temperature. Chlorodiphenylphosphine (5.86 mmol) in THF (10 mL) was added, and the mixture was stirred for 1 hour at 0°C. The mixture was then warmed over a period of 48 hours. Isolation of the product yielded 0.050 g of a tan powder. FTIR: observed a peak at 1665 cm\(^{-1}\) for the carbonyl and weak peak at 1452 cm\(^{-1}\) for the P-Ph bond. Anal. calcd. for...
Isolation of the calcium-substituted cuprates, formed from p-bromopoly styrene and chloromethylated polystyrene, gave dark brown solids under inert atmosphere conditions. The isolation was carried out using Schlenk glassware and done at −45°C with gradual warming to room temperature. Exposure of the solids to air yielded light brown to blue-green colored solids. Elemental analyses of the solids, under an inert atmosphere, showed the presence of copper and nitrogen but not calcium (within detection limits of 0.20%). From the analyses of the polymers, we were unable to quantitatively account for all elements. These results suggest that the calcium can be removed by filtration and washing from the polymer, and that the copper is bound to a carbon on the polymer. The calcium may be in equilibrium with or loosely coordinated with the copper reagent. The calcium enhances the reactivity of the organocopper reagent in subsequent reactions with electrophiles.

**Calcium-Substituted Reagent From p-Bromopoly styrene**

Highly reactive calcium (7.58 mmol) was added to a solution containing p-bromopoly styrene (5.08 mmol Br, based on 2.44 mmol Br/g) in THF (30 mL) and stirred for 18 hours at 0°C. The calcium-substituted reagent was allowed to settle for 1 hour at 0°C and approximately one-half of the filtrate was removed from the polymer. The polymer was then isolated using Schlenk glassware at room temperature and washed with THF (3 × 25 mL), and dried under vacuum at room temperature for 24 hours. Yield = 1.6955 g of a dark brown powder. Anal. Found: C = 3.78, Br = 5.09.

**Calcium-Substituted Reagent From Chloromethylated Polystyrene**

Highly reactive calcium (4.59 mmol) was added to a solution containing chloromethylated polystyrene (3.18 mmol Cl, based on 1.06 mmol Cl/g) in THF (30 mL) and stirred for 6 hours at 0°C. The calcium-substituted reagent was allowed to settle for 1 hour at 0°C. About one-half of the filtrate was removed from the polymer by centrifugation. The polymer was then isolated using Schlenk glassware at room temperature and washed with THF (5 × 25 mL). The polymer was then dried under vacuum at room temperature for 12 hours. Yield = 3.0307 g of a purple-red powder. Anal. Found: C = 2.55, Cl = 1.34.

**Calcium Cuprate Reagent From p-Bromopoly styrene**

Highly reactive calcium (2.10 mmol) was added to a solution containing p-bromopoly styrene (1.41 mmol Br, based on 2.44 mmol Br/g) in THF (30 mL) and stirred for 48 hours at room temperature. The polymer was filtered using Schlenk glassware, and fresh THF (30 mL) was added. The solution was cooled to −45°C at which time CuCN (1.40 mmol) and LiBr (2.83 mmol) in THF (10 mL) were added. The resulting solution was stirred at −45°C for 2 hours. The polymer was filtered at −45°C with slight warming. THF (15 mL) was added. Approximately one-half of the solution was transferred to another flask under argon. The polymer was allowed to settle at room temperature. The filtrate was then removed via cannula. The polymer was dried under vacuum for 6 hours at room temperature. Yield = 0.1595 g of a dark brown/black powder. Anal. Found: C = 77.35, H = 6.90, Cu = 7.85, N = 0.52, Br = 1.10, Ca = 0.20 (detection limit is 0.20%).

**Calcium Cuprate Reagent From Chloromethylated Polystyrene**

Highly reactive calcium (1.77 mmol) was added to a solution containing chloromethylated polystyrene (1.14 mmol Cl, based on 1.06 mmol Cl/g) in THF (30 mL) and stirred for 6 hours at 0°C. The polymer was filtered using Schlenk glassware. Fresh THF (30 mL) was then added. The solution was cooled to −45°C at which time CuCN (1.18 mmol) and LiBr (2.83 mmol) in THF (10 mL) were added. The resulting solution was stirred at −45°C for 2 hours. The polymer was then filtered at −45°C with slight warming to room temperature using Schlenk glassware. THF (15 mL) was added. Approximately one-half of the solution was transferred to another flask already under argon. The polymer was allowed to settle at room temperature, and the filtrate was removed from the polymer by cannula. The polymer was dried under vacuum for 8 hours at room temperature. Yield = 0.5034 g of a dark brown/black powder. Anal. Found: C = 82.78, H = 7.60, Cu = 3.76, N = 0.45, Cl = 0.27, Ca = 0.20 (detection limit is 0.20%).

The foregoing detailed description has been given for clarity of understanding only and no unnecessary limitations are to be understood therefrom. The invention is not limited to the exact details shown and described, for obvious modifications will occur to those skilled in the art.

What is claimed is:

1. A calcium-substituted polymeric compound comprising a polymer substituted with calcium atoms in a covalent interaction, wherein the calcium atoms are derived from a soluble calcium species comprising formally zerovalent calcium metal atoms and a solubilizing agent in an ethereal, polyetheral, or hydrocarbon solvent.
2. The calcium-substituted polymeric compound of claim 1 wherein the polymer comprises pendant aliphatic, aryl, arylalicyl, or heterocyclic groups substituted with calcium atoms.
3. The calcium-substituted polymeric compound of claim 1 wherein the polymer is a substantially inorganic polymer.
4. The calcium-substituted polymeric compound of claim 1 wherein the polymer is insoluble.
5. The calcium-substituted polymeric compound of claim 1 wherein the polymer is soluble.
6. The calcium-substituted polymeric compound of claim 1 wherein the polymer is a substantially organic polymer.
7. The calcium-substituted polymeric compound of claim 6 wherein the organic polymer is an olefinic-based polymer.
8. The calcium-substituted polymeric compound of claim 7 wherein the polymer is a polystyrene-based polymer.
9. A calcium-substituted polymeric compound comprising:

   a) a polymer containing reactive halogen, cyanide, 1,3-diene, or conjugated polyunsaturated groups; and
(b) at least one of said reactive groups further substituted with a calcium atom in a covalent interaction.

10. The calcium-substituted polymeric compound of claim 9 wherein the polymer is a substantially inorganic polymer.

11. The calcium-substituted polymeric compound of claim 10 wherein the organic polymer is an olefinic-based polymer.

12. The calcium-substituted polymeric of claim 11 wherein the olefinic-based polymer is a poly styrene-based polymer.

13. A calcium-substituted polymeric cuprate complex comprising a polymer complexed with calcium atoms and copper atoms, wherein the calcium atoms are derived from a soluble calcium species comprising formally zerovalent calcium metal atoms and a solubilizing agent.

14. The calcium-substituted polymeric compound of claim 13 wherein the copper atoms are derived from a copper(I) salt.

15. The calcium-substituted polymeric cuprate compound of claim 13 further comprising an alkali metal halide.

16. A method of forming a calcium-substituted polymeric compound comprising combining a polymer containing reactive halogen, cyanide, 1,3-diene, or conjugated polyunsaturated groups with a soluble calcium species comprising formally zerovalent calcium metal atoms.

17. The method of claim 16 wherein the soluble calcium species comprises formally zerovalent calcium atoms combined with a solubilizing agent.

18. The method of claim 17 wherein the soluble calcium species is formed from the reduction of a calcium(II) salt in an ethereal, polyether, or hydrocarbon solvent.

19. The method of claim 18 wherein reduction of the calcium(II) salt is carried out using a solubilized reducing agent with a reduction potential of about −1.5 volts or more negative.

20. The method of claim 19 wherein the reducing agent is an alkali metal arenne.

21. A method for preparation of functionalized polymers comprising reacting a calcium-substituted polymeric compound with an organic electrophile to replace the covalently bonded calcium in the calcium-substituted polymeric compound by the organic radical of the electrophile and form the functionalized polymer.

22. The method for preparation of functionalized polymers of claim 21 wherein the calcium-substituted polymeric compound is initially reacted with a copper(I) salt to form a calcium-substituted cuprate polymeric reagent.

23. The method for preparation of functionalized polymers of claim 22 wherein the copper(I) salt is a cyanide or thienyl cyanide.

24. A method for preparation of functionalized polymers comprising:
(a) combining a polymer with a soluble calcium species comprising formally zerovalent calcium metal atoms to form a calcium-substituted polymer having covalently bonded calcium atoms; and
(b) combining an electrophile with the calcium-substituted polymer to form a functionalized polymer.

25. A calcium-substituted polymer prepared by the reaction of a polymer containing at least one reactive site with a soluble calcium species comprising formally zerovalent calcium metal atoms.

26. The calcium-substituted polymeric of claim 25 wherein the polymer is soluble.

27. The calcium-substituted polymeric of claim 25 wherein the polymer is insoluble.

28. The calcium-substituted polymeric of claim 25 wherein the reactive site is selected from the group consisting of halogen, cyanide, 1,3-diene, and a conjugated polyunsaturated group.

29. A calcium-substituted polymeric cuprate prepared by the reaction of a calcium-substituted polymer with a soluble copper(I) salt; wherein the calcium-substituted polymer is prepared by the reaction of a polymer containing at least one reactive site with a soluble calcium species comprising formally zerovalent calcium metal atoms.

30. The calcium-substituted polymeric cuprate of claim 29 wherein the soluble copper(I) salt is selected from a group consisting of a copper(I) cyanide, a copper(I) thienyl cyanide, and a copper(I) halide.
It is certified that error appears in the above-identified patent and that said Letters Patent is hereby corrected as shown below:

Column 11, line 15, "tetramethylethylene" should read --tetramethylethylenediamine--.

INVENTOR(S) : Rieke

It is certified that error appears in the above-identified patent and that said Letters Patent is hereby corrected as shown below:

Column 27, line 55, "Insolation" should read --Isolation--.

Column 28, line 52, "S-(CH₂)" should read --"PS-(CH₂)"--.

Column 30, line 10, "CuCN.2LiBr" should read --CuCN·2LiBr--.

Column 30, line 19, "Clr/g," should read --Cl/g,--.

Column 30, line 26, "Insolation" should read --Isolation--.

Column 30, line 48, "0.881" should read --0.88--.

Column 30, line 52, insert --CN-- after the symbol "\".

Column 30, line 66, "0.881" should read --0.88--.

Column 31, line 48, "0.881" should read --0.88--.

Column 31, line 53, "polymers" should read --Polymers--.

Column 32, line 26, "Si-13C" should read --Si-C--.
It is certified that error appears in the above-identified patent and that said Letters Patent is hereby corrected as shown below:

Column 32, line 52, "0.181" should be --0.18--.

Column 34, line 46, "arylalky" should read --arylalkyl--.

Column 34, line 46, insert --covalently-- after the word "groups".

Column 35, line 4, "inorganic" should read --organic--.

Column 35, line 9, "polymeric" should read --polymer--.

Column 35, line 18, "compound" should read --complex--.

Column 35, lines 21-22 "compound" should read --complex--.

Column 36, line 25, "polymeric" should read --polymer--.
It is certified that error appears in the above-identified patent and that said Letters Patent is hereby corrected as shown below:

Column 36, line 27, "polymeric" should read --polymer--.

Column 36, line 29, "polymeric" should read --polymer--.

Signed and Sealed this
Second Day of August, 1994
