ABSTRACT: Systematic study of the closely related hemiurid genera *Mitrostoma*, *Neopisthadena* and *Opisthadena* revealed that *Opisthadena cortesi* is a junior synonym of *Opisthadena dimidia* and *Opisthadena fujianensis* and *Opisthadena marina* are species inquirendae. Phylogenetic analysis of the 7 recognized species, based on 21 transformation series derived from comparative morphologic characters, produced a single tree with a consistency index of 0.735. The five species of the genus *Opisthadena* constitute a monophyletic clade and *Neopisthadena habei* is their sister group. *Mitrostoma nototheniae* is the sister group of the other 6 members of the clade. Geographic distribution suggests an ancient circum-Pacific distribution of the group. The association between kyphosids and this group of hemiurids appeared with the ancestor of *Neopisthadena* and *Opisthadena*.

The Hemiuridae (sensu Brooks et al., 1985) is 1 of the most diverse, and characteristic, groups of digeneans inhabiting marine fishes. Gibson and Bray (1979) grouped together the genera *Opisthadena* Linton, 1910, *Genolinea* Manter, 1925, *Neotheltrum* Gibson and Bray, 1979, and *Mitrostoma* Manter, 1954 in the subfamily Opisthadeninae. *Neopisthadena* Machida, 1980 was described as a group closely related to *Opisthadena*. *Mitrostoma* and *Neopisthadena* are both monotypic; *Mitrostoma nototheniae* Manter, 1925 was described by Manter (1954) from *Notothenia macrocephala* (Günther) off New Zealand and *Neopisthadena habei* Machida, 1980 was described from *Kyphosus cinerascens* (Forsk.) off Japan (Machida, 1980). *Opisthadena* comprises 8 nominal species. The type species, *Opisthadena dimidia* Linton, 1910, was first described from *Kyphosus sectatrix* (Linn.) and *Kyphosus incisor* (Cuvier and Valenciennes) off Florida (Linton, 1910). *Opisthadena dimidia* was subsequently recorded in *Kyphosus* spp. off Florida (Manter, 1947; Overstreet, 1969), the Pacific coast of Panama and the Caribbean Sea (Sogandares-Bernal, 1959), South Australia (Manter, 1966), Japan (Machida, 1980), the Caribbean Sea (Sierra, 1984), and the Pacific coast of México (León-Règagnon et al., 1997). The other species of *Opisthadena* have restricted geographic distributions. *Opisthadena kuwaiti* Al-Yamani and Nahhas, 1981 was described from the Arabian Gulf in *Valamugil seheli* (Forsk.) (Al-Yamani and Nahhas, 1981). *Opisthadena cortesi* Bravo-Hollis, 1965 was described from *Kyphosus elegans* (Peters) off the Gulf of California (Bravo-Hollis, 1965). Yamaguti (1970) described *Opisthadena kyphosi* Yamaguti, 1970 from *Kyphosus cinerascens* off Hawaii. *Opisthadena bodogensis* Johnson and Copsey, 1953 and *Opisthadena cheni* Martin, 1978 were described off the coast of California from *Cebidichthys violaceus* (Girard) (Johnson and Copsey, 1953) and *Girella nigricans* (Ayers) (Martin, 1978), respectively. Finally, Tang et al. (1983) described *Opisthadena fujianensis* Tang, Shi, Cao, Guan and Pan, 1983 and *Opisthadena marina* Tang, Shi, Cao, Guan and Pan, 1983 from Fujian, China, in *Mugil engeli* (Bleeker) and *Ambassis gymnocephalus* (Lacépède), respectively.

This study was undertaken to propose a hypothesis of the phylogenetic relationships of the species of *Opisthadena*, *Ne-*

pisthadena, and *Mitrostoma*, and to examine the biogeographic and coevolutionary history of the group.

MATERIALS AND METHODS

Specimens examined

We examined all available published sources and the following specimens (species name followed by accession number (), number of examined specimens [], host, and locality): Colección Nacional de Helminthos, México City, México (CNHE): *O. cortesi* (898 P, 1379 P, 1483 P) [24] *K. elegans*, Baja California, México; *O. dimidia* (899 P, 2631 P, 2632 P) [9] *K. incisor*, Quintana Roo and *K. elegans*, Jalisco, México; *Genolinea dactylopagri* Manter, 1954 (2485 P) [1] *Dactylopagrus macropterus* (Forster), New Zealand; *Genolinea laticauda* Manter, 1925 (807 P) [9] *K. elegans*, Sonora, México; *Neotheltrum lissosomum* Manter, 1940 (1517 P) [1] "Angel fish," Socorro Island, México; *Neotheltrum gravidum* Manter, 1940 (999 P) [1] *Abudefduf saxatilis* (Linn.), Socorro and Clarión Islands, México; *Parahemiurus merus* (2633–2641 P) [53] *Harengula thrissina* (Jordan and Gilber) and *Opisthonema libertate* (Günther), Jalisco, México. United States National Parasite Collection, Beltsville, Maryland, U.S.A. (USNPC): *O. dimidia* (8489, 77751) [3] *K. sectatrix*, Florida and Puerto Rico; *O. bodogensis* (37338) [1] *C. violaceus*, California; *O. kyphosi* (63790) [5] *K. cinerascens*, Hawaii; *M. nototheniae* (49150) [1] *Notothenia macrocephala*, New Zealand; *Genolinea dactylopagri* (49151) [1] *D. macropterus*, New Zealand; *Genolinea anura* Layman, 1930 (49177) [1] *Chironemus spectabilis* (Hutton), Australia; *Genolinea montereyensis* Annereaux, 1947 (36952) [1] *Clinocottus analis* (Girard), California; *Genolinea noblei* Nahhas and Cable, 1964 (60290) [1] *A. saxatilis*, Jamaica. Meguro Parasitological Museum, Tokyo, Japan (MPM): *O. kyphosi* (15245) [4] *K. cinerascens*, Japan. National Science Museum Tokyo, Japan (NSMT): *N. habei* (PI 2293) [5] *K. cinerascens*, Japan; *O. dimidia* (PI 2234) [3] *K. cinerascens*, Japan. We were unable to establish contact with the Hancock Parasite Collection (University of Southern California), where *Opisthadena cheni* is reportedly deposited. Moreover, the location of type specimens was not indicated in the original descriptions of *Opisthadena kuwaiti*. Therefore, we based our character analysis for these 2 species on the original descriptions.

Analyses performed

Phylogenetic analyses were performed using the methods of phylogenetic systematics (Hennig, 1966; Wiley, 1981; Wiley et al., 1991). Results were confirmed quantitatively using the PAUP (Phylogenetic Analysis Using Parsimony) computer program version 3.1.1. (Swofford, 1993), run on a Macintosh LCIII computer. The following options were examined: (1) characters: all unordered, or only character 18 unordered. (2) Outgroups: plesiomorphic conditions determined by the state observed in the genera *Genolinea* and *Neotheltrum*, which are recognized to be the most related genera of bunocotylids (Gibson and Bray, 1979) as a primary outgroup and the Hemiurini (*Hemiurus*, *Parahemiurus*, and *Anahemiurus*). The hemiurids were recognized to be the sister group of bunocotylids by Brooks et al. (1985) and within them, the hemiurini were considered to be the most related group of the bunocotylids (Gibson and Bray, 1979). (3) optimization: Acctran, Deltran. (4) Tree-building algorithms: exhaustive search.

Received 20 March 1996; revised 28 June 1996; accepted 28 June 1996.

* Department of Zoology, University of Toronto, Toronto, Ontario, Canada M5S 1A1.

TABLE I. Data matrix for *Opisthadenia*, *Neopisthadenia*, and *Mitrostoma*. Characters are numbered as in the text; for descriptions of characters and polarity arguments, see text. 0 = plesiomorphic condition; 1, 2 = apomorphic conditions; ? = condition unknown.

RESULTS

Taxa recognized

Of the 10 nominal species in this group, we recognize 7 as valid in this study; 5 species of *Opisthadenia* and the monotypic *Neopisthadenia habei*, and *Mitrostoma nototherniae*. Overstreet (1969) synonymized *O. cortesi* with *O. dimidia*. We examined the type specimens of *O. cortesi* and agree with Overstreet's evaluation. Machida (1980) proposed that *O. kyphosi* was synonymous with *O. dimidia*. He argued that the number of oral papillae was not a useful character for distinguishing species because in Japanese specimens of *O. dimidia* the number of oral papillae varied from 5 pairs, as originally described by Manter (1947), to 3 pairs. We have noticed the same variation in number of papillae in the specimens of *O. dimidia* that we examined, but we also found that at least 3 pairs of oral papillae are always present. *Opisthadenia kyphosi*, by contrast, bears no oral papillae, and for that reason we consider it a valid species. Finally, *O. fujianensis* and *O. marina* were described based on a single specimen each, and the characters used to separate them from other species, such as body length, the presence of annulations in the tegument, and the shape of the genital cone, vary greatly with fixation techniques. The shape of vitelline masses in *O. fujianensis* indicates that this specimen might belong in the Lecithasterinae (sensu Brooks et al., 1985), and the male genital ducts of *O. marina* differ greatly from those of other members of *Opisthadenia*. We therefore consider those taxa species inquirendae in this analysis.

Character argumentation

We used the following characters and their states in the phylogenetic analysis (characters are listed in order of their appearance in Table I; 0 = plesiomorphic; 1, 2 = apomorphic; ? = unknown). The polarity argumentation for each character is:

1. Seminal vesicle. Three states: 0 = saccate; 1 = tubular; 2 = seminal sac. In the species of the genus *Opisthadenia* there is a sac containing a very coiled tubular seminal vesicle.
2. Egg size. Two states: 0 = larger than 25 μm ; 1 = 13–18 μm .

3. Pharynx size. Two states: 0 = pharynx smaller than the oral sucker; 1 = pharynx and oral sucker the same size.
4. Testes location. Two states: 0 = in the second third of the body; 1 = in the posterior third of the body.
5. Excretory ducts. Two states: 0 = nonbranched anteriorly to the acetabulum; 1 = branched anteriorly.
6. Oral papillae. Two states: 0 = absent; 1 = present. As noted above, the number of oral papillae is variable within a species.
7. Testes position. Three states: 0 = symmetrical; 1 = oblique; 2 = tandem. In most of the genera of the Hemiurini (outgroup) testes are symmetrical, so we considered this state as plesiomorphic.
8. Distance between posterior testis and ovary. Two states: 0 = posterior testis lies more than its own length from the ovary; 1 = posterior testis lies less than its own length from the ovary.
9. Location of the vitellaria and ovary. Two states: 0 = in the third quarter of the body; 1 = in the fourth quarter of the body.
10. Muscular sphincter around acetabulum. Two states: 0 = absent; 1 = present.
11. Seminal vesicle wall. Two states: 0 = thin; 1 = thick.
12. End of pars prostatica. Three states: 0 = at the level of acetabulum; 1 = posterior to the acetabulum; 2 = anterior to the acetabulum.
13. Acetabular papillae. Two states: 0 = absent; 1 = present. This is a unique state for *O. cheni*.
14. Extension of excretory ducts. Two states: 0 = running forward of the acetabulum; 1 = forward of the acetabulum and back posteriorly to testes level.
15. Postacetabular transverse fold. Two states: 0 = absent; 1 = present. In the description of the Arabian species, there is no mention made of the presence or absence of the fold. Because we could not examine type specimens, we coded this character as "unknown" (?).
16. Ejaculatory duct. Two states: 0 = absent; 1 = present.
17. Seminal receptacle. Two states: 0 = absent; 1 = present.
18. Preacetabular pit. Two states: 0 = absent; 1 = present.
19. Excretory vesicle bifurcation. Two states: 0 = near the posterior margin of the acetabulum; 1 = at the level of testes.

FIGURE 1. Phylogenetic tree for *Mitrostoma nototheniae*, *Neopisthadena habei*, and 5 species of *Opisthadena*. Numbers accompanying slash marks on the tree indicate putative synapomorphies (character number followed by character state in parentheses) supporting the phylogenetic relationships. For identities of characters, refer to text. Bold numbers, convergent or parallel character state; *, reversal. For character 3, it is equally parsimonious to postulate that state "1" is a synapomorphy of *O. cheni*, *O. bodegensis*, *O. kyphosi*, and *O. dimidia*, with a reversal to state "0" in *O. kyphosi* plus *O. dimidia*, with no change in postulated relationships.

The condition of this character is not described in detail for *O. kuwaiti* and *O. cheni*, we coded this character as "unknown" (?) for those two species.

20. Uterine seminal receptacle. Two states: 0 = present; 1 = absent.
21. Vitelline masses position. Three states: 0 = symmetrical; 1 = oblique; 2 = tandem.

Phylogenetic analysis of Bunocotylinae

Phylogenetic analyses of the 7 taxa we consider valid, using all combinations of above options, produced a single most parsimonious phylogenetic tree (Fig. 1), with a consistency index of 0.735 (34 transformations to account for 25 apomorphic states). This result predicts that *O. kuwaiti* possesses a postacetabular fold and that *O. kuwaiti* and *O. cheni* possess excretory vesicles that bifurcate at the level of the testes; verification of these predictions requires examination of specimens. Only 2 of the 34 evolutionary changes postulated by this tree represent an evolutionary loss (the loss of oral papillae in *O. kyphosi* and *O. kuwaiti*), indicating a minimal amount of secondary simpli-

fication in the evolution of these parasites. The loss of the ec-soma and cuticular plications present in the Hemiurini are not considered herein because those are the result of a previous simplification event in some basal point of the ancestral states of bunocotilids. The tree supports the monophyly of *Mitrostoma* + *Neopisthadena* + *Opisthadena*; the presence of a postacetabular transverse fold is the synapomorphy diagnosing the clade. The tree further suggests that the monotypic *Mitrostoma* is the sister group of the remaining species and *Neopisthadena habei* is the sister species of the genus *Opisthadena*, which is monophyletic.

DISCUSSION

The level of homoplasy encountered in this study is comparable to those found in other phylogenetic systematic studies of digeneans (Brooks and McLennan, 1993a, 1993b; Pérez-Ponce de León and Brooks, 1995a, 1995b), although substantially less than postulated by intuitive or evolutionary taxonomic studies (e.g., Pearson, 1992). The low amount of simplification in this genera of bunocotilids provides additional support

FIGURE 2. Optimization of geographic distribution and hosts onto phylogenetic tree for *Mitrostoma*, *Neopisthadena*, and *Opisthadena* species.

for previous observations by Brooks and McLennan (1993a, 1993b) and Pérez-Ponce de León and Brooks (1995a, 1995b) that parasitic platyhelminths seem to have experienced little secondary simplification during their evolutionary history.

Manter (Van Cleave and Manter, 1948; Manter, 1949, 1965) considered the reef fish genus *Kyphosus* to be an interesting system for biogeographic and coevolutionary studies using helminth parasites. *Kyphosus* spp. and their helminth fauna laid the cornerstone for Manter's thoughts about what he called "parascript" (see Brooks and McLennan, 1993a). Manter (1965) proposed an Indo-Pacific origin of *Kyphosus*, with secondary dispersion to the Americas via Japan and Hawaii and to the Caribbean Sea via the eastern Pacific Ocean. Several *Opisthadena* species inhabit kyphosid and related girellid hosts,

so this study provides an opportunity to examine Manter's ideas in the light of current methods of phylogenetic and biogeographic analysis.

The phylogenetic tree depicts *Mitrostoma nototherniae* from New Zealand as the sister species of the rest of the clade (Fig. 2). The next branching point separates *Neopisthadena habei*, found in Japan from the 5 species of *Opisthadena* found in the Arabian Sea, Pacific Ocean, and Caribbean Sea. The New Zealand, then Japan plus Arabian Sea, and American Pacific distributions suggest a circum-Pacific ancient distribution of the group. Within the *Opisthadena* clade, the Arabian species *O. kuwaiti* is the sister species of the rest. The next 2 species, *O. cheni* and *O. bodegensis*, occur along the California coast. *Opisthadena bodegensis* is the sister species of *O. kyphosi*, the

Hawaiian endemic, plus *O. dimidia*, which is widely distributed throughout the Pacific Ocean and is the only member of the genus currently known from the Caribbean Sea. This particular geographic pattern does not support Manter's view of a progressive dispersion from the western to the eastern Pacific Ocean, suggesting rather that the Hawaiian endemic and its widespread sister species are derived from the eastern Pacific Ocean. The geographic distribution of *O. dimidia* is also interesting. Other hemiurids, such as *Derogenes varicus*, are extremely widespread in the marine environment, but those species tend to exhibit little host specificity. *Opisthadena dimidia*, by contrast, inhabits only members of the genus *Kyphosus*. The species is found in geographic areas lacking other members of the genus (the Caribbean Sea and Australia) and also sympatrically with its sister species, *O. kyphosi*, and with non-sister species inhabiting kyphosids and girellids (*O. habei* and *O. cheni*). Its occurrence in the Caribbean Sea supports Manter's (1965) views of colonization of the Caribbean Sea from the eastern Pacific Ocean. Because *O. dimidia* is a highly derived, rather than a basal, member of its clade, it is not reasonable to suggest that it is a widespread ancestral generalist from which the other members of the group are derived. Its distribution pattern is more likely the result of secondary colonization of areas and hosts that are suitable for its survival (the occurrence of its sister species in the same species of host in Hawaii might indicate that *O. kyphosi* originated as a result of allopatric speciation). It is also possible that the widespread occurrence of *O. dimidia*, including its presence in the Caribbean Sea, is the result of anthropogenic phenomena, thus representing recent dispersal of the species. In either case, the species is a highly successful colonizer.

Four species of *Opisthadena* and *Neopisthadena* (*O. dimidia*, *O. kyphosi*, *N. habei*) are restricted to fishes of the Kyphosidae or the related Girellidae (*O. cheni*) and they, together with *O. kuwaiti* and *O. bodegensis*, which do not inhabit kyphosids or girellids, constitute a clade in the phylogenetic tree. The hosts for *Mitrostoma nototheniae* and for *Genolinea* and *Neotheletrum* are not kyphosids or girellids, suggesting that the association between kyphosids and girellids and this clade of digeneans originated with the common ancestor of *Opisthadena* plus *Neopisthadena*. If so, the occurrence of *O. kuwaiti* and *O. bodegensis* in a host that is neither a kyphosid nor a girellid would best be interpreted as the result of speciation via host switching (a form of peripheral isolates allopatric speciation, see Brooks and McLennan, 1993a).

The host and geographic distribution patterns discussed above make it difficult to interpret the degree of evolutionary association between kyphosids and girellids and *Opisthadena*. A possible solution would be to treat *Opisthadena* as a single data source, then assemble additional phylogenetic trees for other parasite groups inhabiting the same hosts and combine them in a single analysis to see if the parasite groups supported any general geographic or host relationships (Brooks parsimony analysis in Wiley, 1988a, 1988b; Brooks, 1981, 1990; Brooks and McLennan, 1991, 1993a). In this case, phylogenetic studies of groups such as *Cadenatella* Dollfus, 1948, *Jeancadenatia*, Dollfus, 1948, *Enenterum* Linton, 1910, *Deontacylix* Linton, 1910 (Digenea), and *Filisoma* Van Cleave, 1928 (Acanthocephala) could provide the additional parasite data necessary to ask if the geographic distribution and host patterns indicated by

Opisthadena are unique to that group or are part of a general pattern of marine evolutionary diversification.
