ABSTRACT

Five mouse anti-human butyrylcholinesterase (BChE) monoclonal antibodies bind tightly to native human BChE with nanomolar dissociation constants. Pairing analysis in the Octet system identified the monoclonal antibodies that bind to overlapping and independent epitopes on human BChE. The nucleotide and amino acid sequences of 4 monoclonal antibodies are deposited in GenBank. Our goal was to determine which of the 5 monoclonal antibodies recognize BChE in the plasma of animals. Binding of monoclonal antibodies 11D8, B2 18–5, B2 12–1, mAb2 and 3E8 to BChE in animal plasma was measured using antibody immobilized on Pansorbin cells and on Dynabeads Protein G. A third method visualized binding by the shift of BChE activity bands on nondenaturing gels stained for BChE activity. Gels were counterstained for carboxylesterase activity. The three methods agreed that B2 18–5 and mAb2 have broad species specificity, but the other monoclonal antibodies interacted only with human BChE, the exception being 3E8, which also bound chicken BChE. B2 18–5 and mAb2 recognized BChE in human, rhesus monkey, horse, cat, and tiger plasma. A weak response was found with rabbit BChE. Monoclonal mAb2, but not B2 18–5, bound pig and bovine BChE. Gels stained for carboxylesterase activity confirmed that plasma from humans, monkey, pig, chicken, and cow does not contain carboxylesterase, but plasma from horse, cat, tiger, rabbit, guinea pig, mouse, and rat has carboxylesterase. Rabbit plasma carboxylesterase hydrolyzes butyrylthiocholine. In conclusion monoclonal antibodies B2 18–5 and mAb2 can be used to immuno extract BChE from the plasma of humans, monkey and other animals.

1. Introduction

Butyrylcholinesterase (BChE; EC 3.1.1.8) is a serine esterase that catalyzes the hydrolysis of acetylcholine, butyrylcholine, benzoylcholine, indoxyl acetate, p-nitrophenyl acetate, phenyl acetate, alpha-naphthyl acetate, aspirin, procaine, succinylcholine,

mivacurium, cocaine, heroin, irinotecan, bambuterol and octanoyl ghrelin [1–4]. Some of these esters are used as drugs to treat various human conditions. BChE also serves as a stoichiometric bioscavenger for organophosphorus pesticides and nerve agents, thus protecting acetylcholinesterase from irreversible inhibition by these toxic compounds [5].

Many drugs are synthesized as esters to neutralize their charge, thus allowing the drug to be absorbed through the gut and through cell membranes including cells in the brain. The esterified drug may be a prodrug that requires hydrolysis of the ester bond to become the active drug. For example, the antiasthma prodrug bambuterol is hydrolyzed to the active drug terbutaline by BChE [6]. Other ester drugs are detoxified by BChE. For example, BChE hydrolyzes cocaine to the pharmacologically inactive metabolites, ecgonine methyl ester and benzoic acid [7–9]. New drugs are tested in

Abbreviations: HuBChE, human butyrylcholinesterase; BSA, bovine serum albumin; CES, carboxylesterase; U, units of activity.

animals before they are tested in humans. Standard laboratory animals including the mouse, rat, guinea pig, and monkey have levels of BChE in plasma that are not representative of the level of BChE in human plasma. The rat has 30-fold less plasma BChE compared to humans. Rhesus monkey has 2–3 fold higher levels of BChE in plasma than humans. Another difference between animals and humans is that mouse, rat, and guinea pig have carboxylesterase in plasma, whereas humans and monkeys have none [4]. The plasma carboxylesterase in animals degrades drug esters rapidly, giving an inaccurate pharmacokinetic profile for drug metabolism in humans. The plasma carboxylesterase knockout mouse, ES1–/– (Jackson Laboratory stock number 014096), can be used as a model for how humans metabolize an ester drug [10,11].

Knowledge of the identity of the esterase involved in metabolism of a drug is important because it leads to an understanding of individual differences in response to drugs. The atypical and silent variants of human BChE do not hydrolyze succinylcholine and mivacurium; consequently people with these genetic variants are unable to breathe for up to 2 h from a dose intended to paralyze for 3 min [12]. More than 70 variants of human BChE have been recognized [13]. Animal studies that aim to identify the role of BChE in drug metabolism may benefit by using an immobilized antibody to capture BChE. The captured BChE has activity and can be used directly to measure the role of BChE in ester hydrolysis, as we have done for octanoyl ghrelin [14]. Mrvova et al. produced two monoclonal antibodies in BChE knockout mice that recognize BChE in mouse, rat and dog plasma [15].

In a previous report [16] we characterized 5 mouse anti-human BChE monoclonal antibodies. We reported similar nanomolar binding affinities for all 5 monoclonal antibodies, but variable performance in their ability to immunopurify BChE from human plasma. Octet pairing analysis was carried out by immobilizing pure human BChE on a chip followed by measurement of the change in the interference pattern when antibody flowed over the chip. Pairing analysis showed that two pairs of antibodies, mAb2 and B2 12–1, as well as mAb2 and 3E8, bound to independent epitopes on human BChE and were therefore useful in sandwich assays. We deposited the nucleotide and amino acid sequences of 4 monoclonal antibodies in GenBank. The goal of the present work was to identify the monoclonal antibodies that recognize BChE in the plasma of animals. We describe 5 monoclonal antibodies to human BChE, two of which have broad specificity enabling them to recognize BChE in the blood of human, monkey, horse, cat, and tiger.

2. Materials and methods

2.1. Reagents

2.1.1. Pansorbin cells 1 g (Calbiochem #507862) coated with 1 ml of rabbit anti-mouse IgG H + L (Jackson ImmunoResearch #315-001-003)

Dynabeads Protein G (Life Technologies #10004D). Immuno-Pure Immobilized Protein G (Pierce #20398). Human plasma Na Citrate pooled from 10 donors (UNMC blood bank); rhesus monkey plasma Na Heparin and horse serum (Atlanta Biologicals); cat plasma Na Citrate (Pel-Freez); Bengal Tiger plasma EDTA anticoagulant (Omaha Henry Doorly Zoo); New Zealand white rabbit plasma Na Heparin, porcine serum, and rat serum (RJO Biologicals); guinea pig plasma Na Heparin and mouse strain 129 serum (Taconic); chicken plasma Na Heparin (Innovative Research Inc.); bovine calf serum (General Scientific Lab). Acetylthiocholine iodide, butyrylthiocholine iodide and ethopropazine hydrochloride (Sigma–Aldrich).

2.1.2. Monoclonal antibodies to HuBChE

Mouse anti-human BChE monoclonal antibodies were from the following sources. Monoclonal 3E8 was purchased from Thermo Scientific Pierce (HAH 002-01-02); the original 3E8 monoclonal was made in Denmark [17]. Hybridoma cell line 11D8 was a gift from Dr. Eric Krejci and Dr. Anna Hrabovska [18]. We purified the 11D8 monoclonal from culture medium on Protein G-Sepharose. Hybridoma cell lines B2 18–5 and B2 12–1 were a gift from Dr. Stephen Brimijoin [19]. The cells, having been stored at –80 °C for 30 years, failed to grow but their RNA was still intact. Syd Labs Inc (Natick, MA) made the B2 18–5 and B2 12–1 monoclonal antibodies by recombinant DNA methods using mRNA as a template to make cDNA, followed by ligation of the cDNA into vectors that contained the constant regions, coexpression of the light and heavy chains in Chinese Hamster Ovary cells, and purification on protein A-Sepharose. Ascites fluid from B2 18–5 and B2 12–1 was available for comparison to the recombinant antibodies. The mAb2 monoclonal was made in France [20]. We purified mAb2 from ascites fluid.

2.2. Nucleotide and amino acid sequences of monoclonal antibodies

The nucleotide and amino acid sequences of mouse anti human BChE monoclonal antibodies are deposited in the NCBI databank under accession numbers KJ141199 and KJ141200 for mAb2, KT189143 and KT189144 for B2 18–5, KT189145 and KT189146 for B2 12–1, and KT189147 and KT189148 for 11D8. Use of these monoclonal antibodies for immunoextraction of BChE from human plasma is described in Ref. [16].

2.3. BChE activity

BChE activity was measured in 0.1 M potassium phosphate pH 7.0 at 25 °C with 1 mM butyrylthiocholine iodide in the presence of 0.5 mM 5,5'-dithiobis(2-nitrobenzoic acid) on a Gilford spectrophotometer interfaced to a MacLab data recorder (ADInstruments, Inc.). For example, a 4 ml cuvette received 1.91 ml buffer, 0.05 ml of 20 mM DTNB in buffer, 0.02 ml of 0.1 M butyrylthiocholine dissolved in water, and 0.02 ml plasma. The increase in absorbance at 412 nm was recorded for 1 min and converted to micromoles butyrylthiocholine hydrolyzed using the extinction coefficient 13,600 M^{–1} cm^{–1} [21]. Units (U) of activity are expressed as micromoles per min.

2.4. Immunoabsorbance of BChE to monoclonal antibodies immobilized on pansorbin

Pansorbin® cells are an inexpensive alternative to Dynabeads-Protein G for assessing species selectivity of 5 monoclonal antibodies. Pansorbin® cells are heat-killed, formalin-fixed *Staphylococcus aureus* cells that bear a high cell-surface density of protein A.

The Pansorbin assay was performed as described by Brimijoin et al. [19]. The effectiveness of Pansorbin for binding mouse monoclonal antibodies is enhanced when Pansorbin cells are coated with rabbit anti-mouse IgG. Therefore, the first step in the protocol was to incubate 1 g of washed Pansorbin cells suspended in 9 ml of 50 mM TrisHCl pH 7.4 containing 0.1% BSA with 1 ml of 1 mg/ml rabbit anti-mouse IgG at 37 °C overnight. A 0.1 ml aliquot of rabbit anti-mouse IgG Pansorbin cell suspension was washed and incubated with 1 µg monoclonal in a total volume of 0.2 ml overnight. The control incubation contained Pansorbin cells and buffer, but no monoclonal. Unbound monoclonal was washed off. The washed Pansorbin complex was incubated overnight at room temperature on a rotating mixer with plasma or serum containing 13.5 milliunits of BChE supplemented with 50 mM TrisHCl pH 7.4/

0.1% BSA to total 0.2 ml. Plasma or serum was from human, rhesus monkey, horse, domestic cat, Bengal tiger, New Zealand white rabbit, pig, guinea pig, mouse, chicken, or adult cow. Rat plasma and bovine serum were added to the cells without buffer.

The Pansorbin cells were pelleted by centrifugation at 5000 rpm for 4 min. The supernatant was assayed for unbound BChE activity. The pellets were washed twice with 1 ml buffer and finally with 1 ml of 0.1 M potassium phosphate, pH 7.0. The activity of BChE bound to Pansorbin cells was determined by measuring the yellow color that developed after addition of 1 ml Ellman reagent (1 mM butyrylthiocholine, 0.5 mM 5,5'-dithiobis(2-nitrobenzoic acid) in 0.1 M potassium phosphate pH 7.0) to the washed pellet. The reaction was stopped after 10 min by addition of 20 μ l of 2.0 mM ethopropazine, a specific inhibitor of BChE activity. After centrifugation at 12,000 rpm for 10 min to pellet the turbidity from Pansorbin cells, absorbance of the supernatant was read in the Gilford spectrophotometer at 412 nm. Fig. 1A illustrates antibodies and BChE bound to Pansorbin and detection of bound BChE by measurement of bound BChE activity.

2.5. Dynabeads-Protein G for immunopurification of BChE from plasma or serum

Immunopurification of HuBChE from human plasma in a single step was developed by Sporty et al. to enable mass spectrometry diagnosis of exposure to chemical nerve agents [22]. In the present work we used the Sporty protocol to compare 5 monoclonal antibodies for ability to extract BChE from the plasma or serum of animals. We evaluated the quantity of BChE bound by comparing BChE activity in the unbound fraction to BChE activity in plasma before treatment with Dynabeads.

In brief, 100 μ l of Dynabeads-Protein G suspension was washed three times with 200 μ l of PBS, followed by incubation overnight with 20 μ g of monoclonal antibody in 0.4 ml PBS containing 0.05% Tween-20. The Dynabead complex was washed twice with 200 μ l of triethanolamine buffer (0.2 M triethanolamine, 0.025% NaN₃, pH 7.8), before the complex was crosslinked with 200 μ l of dimethyl pimelimidate (5.4 mg/ml) in triethanolamine buffer for 30 min. The crosslinking solution was discarded and residual agent was inactivated by incubating the beads for 15 min in 20 mM TrisHCl pH 7.5. Beads were washed 3 times with 200 μ l of PBS, 0.05% Tween-20 before they were incubated with 0.5 ml human, monkey, horse, cat, guinea pig, mouse and chicken plasma or serum, and 5 ml rabbit, pig, rat or bovine plasma or serum overnight at room

temperature in a rotating mixer. We did not have enough tiger plasma to assay binding of tiger BChE to Dynabeads. BChE activity assays were used to evaluate the quantity of BChE bound. Fig. 1B shows BChE enzyme captured by anti-BChE antibody immobilized on Dynabeads Protein G and detection of bound BChE by measurement of bound BChE activity.

2.6. Nondenaturing polyacrylamide gel electrophoresis

Animal plasma or serum samples (5 μ l) were incubated 3 h at 25 °C with or without 10 μ l of monoclonal B2 18–5 (0.9 mg/ml) or 10 μ l of mAb2 (0.6 mg/ml) for 3 h at 25 °C before they were diluted with an equal volume of 50% glycerol, 0.1% bromphenol blue. Samples were loaded on nondenaturing 4–30% gradient polyacrylamide gels and electrophoresed at 250 V constant voltage for 20 h at 4 °C. The gels were stained for BChE activity by the method of Karnovsky and Roots [23]. The staining solution contained 180 ml of 0.2 M maleic acid adjusted to pH 6.0 before use, 15 ml of 0.1 M sodium citrate, 30 ml of 0.03 M CuSO₄, 30 ml of water, 30 ml of 5 mM potassium ferricyanide, and 0.18 g butyrylthiocholine iodide to make 2 mM butyrylthiocholine. Gels were incubated in the buffer for 2 h with gentle shaking until brown-red bands appeared. Gels were counterstained for carboxylesterase (CES) activity by incubating them in 100 ml of 50 mM TrisHCl pH 8.0 to which was added 50 mg of alpha-naphthylacetate in 1 ml ethanol to make 2.7 mM, and 50 mg of solid Fast Blue RR [4]. Green bands developed within a few minutes.

2.7. Comparison of BChE amino acid sequences

The protein sequence of HuBChE was compared with the BChE sequences of rhesus monkey, horse, cat, Bengal tiger, pig, guinea pig, mouse, rat, chicken, and cow using BLASTP 2.2.30+ [24]. The sequence comparison results are presented as percent identity.

3. Results

3.1. Butyrylcholinesterase activity in animal plasma or sera

BChE activity varied widely between species. Table 1 shows the highest BChE activity in Rhesus monkey plasma, similar BChE activities in human, horse, and mouse, low activity in the cat, tiger, rabbit, pig, and chicken, and barely detectable BChE activity in rat plasma and adult bovine serum.

Fig. 1. Schemes for antibody binding to Pansorbin and Dynabeads Protein G. A) Protein A on the surface of Pansorbin is coated with anti-mouse IgG to enhance binding of mouse anti-BChE monoclonal antibody. The pansorbin antibody complex is incubated with plasma to allow capture of BChE by the anti-BChE IgG. The bound BChE retains enzyme activity and is detected by hydrolysis of butyrylthiocholine. B) Protein G on the surface of Dynabeads is crosslinked to anti-BChE monoclonal antibody. The Dynabeads Protein G antibody complex is incubated with plasma to capture BChE. Bound BChE is detected by measuring BChE activity in the Dynabeads complex, or alternatively by measuring the loss of BChE activity from plasma.

Table 1
BChE activity in plasma or serum.

Species	BChE activity, U/ml ^a
Human (<i>Homo sapiens</i>) plasma	2.50 ± 0.02
Rhesus monkey (<i>Macaca mulatta</i>) plasma	5.00 ± 0.18
Horse (<i>Equus caballus</i>) serum	2.26 ± 0.10
Cat (<i>Felis catus</i>) plasma	0.40 ± 0.01
Bengal Tiger (<i>Panthera tigris tigris</i>) serum	0.60 ± 0.01
Rabbit (<i>Oryctolagus cuniculus</i>) plasma	0.13 ± 0.03
Pig (<i>Sus scrofa domestica</i>) serum	0.19 ± 0.01
Guinea pig (<i>Cavia porcellus</i>) plasma	1.26 ± 0.06
Mouse (<i>Mus musculus</i>) serum	2.51 ± 0.11
Rat (<i>Rattus norvegicus</i>) plasma	0.058 ± 0.012
Chicken (<i>Gallus gallus</i>) plasma	0.30 ± 0.02
Cow (<i>Bos taurus</i>) serum	0.05 ± 0.02

^a BChE activity was assayed in quadruplicate.

3.2. B2 18–5 and mAb2 recognize butyrylcholinesterase from different species

The reactivity of five anti-human BChE monoclonal antibodies with BChE in the blood of animals was compared by measuring immunoabsorbance to monoclonal antibodies immobilized on Pansorbin cells or Dynabeads Protein G. The percent BChE bound to Pansorbin cells was calculated by measuring the BChE activity bound to Pansorbin cells. The percent BChE bound to Dynabeads was calculated by comparing BChE activity in the unbound supernatant to activity in plasma/serum. The results in Fig. 2A for assays performed with Pansorbin are similar to the results in Fig. 2B for assays with Dynabeads Protein G, with some exceptions. The Pansorbin assay used a constant quantity of BChE activity (13.5 milliunits) whereas the Dynabeads Protein G assay used a constant volume of plasma (0.5 ml) per incubation reaction, except for rabbit, pig, rat, and cow where the volume of plasma was 5 ml. Fig. 2A shows that in the Pansorbin assay all 5 monoclonal antibodies bound 45–60% of the 13.5 milliunits of BChE activity in human plasma. Fig. 2B shows that in the Dynabeads assay B2 18–5 and B2 12–1 captured nearly 100% of the BChE activity in 0.5 ml human plasma, while mAb2 and 3E8 captured 60–70%, and 11D8 captured 10% of the BChE in human plasma. Monoclonal antibodies 11D8 and B2 12–1 bound human BChE exclusively, whereas 3E8 bound human and chicken BChE. Chicken BChE was captured by 20 µg 3E8 in the Dynabeads assay, but not by 1 µg 3E8 in the Pansorbin assay.

Monoclonal antibodies B2 18–5 and mAb2 had the broadest species specificity, capturing BChE in human, rhesus monkey, horse, cat, and rabbit plasma/serum. B2 18–5 and mAb2 also captured BChE in the plasma of Bengal tiger in the Pansorbin assay. We have no data for tiger BChE in the Dynabeads assay because the quantity of tiger plasma available to us was limited. The BChE in pig, guinea pig, mouse, rat, chicken, and cow plasma/serum was not recognized by B2 18–5. However, pig and cow BChE were captured by mAb2, though the quantity captured was low because these animals have low BChE activity in plasma. The low BChE activity in pig and cow plasma resulted in large values for the standard deviation.

BChE activity without and with monoclonal antibody was visualized on nondenaturing gels stained for BChE activity. In Fig. 3, 5 µl of plasma or serum samples were loaded per lane. Band intensities correlate with BChE activities reported in Table 1. Animal plasma or sera that have BChE activity of 0.4–5 U/ml (human, monkey, horse, cat, tiger, guinea pig and mouse) have strong bands of BChE activity in Fig. 3A lanes 1, 3, 5, 7, 9, 15 and 17. However, animal plasma or sera that have BChE activity of 0.04–0.3 U/ml (rabbit, pig, rat, chicken, and cow) have weak bands of BChE activity

in Fig. 3A lanes 11, 13, 19, 21, and 23.

The tetramer band of human BChE, C4, has a molecular weight of 340,000 Da. The dimer band, C3, is composed of two identical BChE subunits. However the dimer band, C2, consists of one BChE subunit and one albumin molecule linked via a disulfide bond [25]. Fig. 3A shows that human, horse, cat, tiger, and mouse have a C2 band, but monkey and guinea pig do not. The monomer band, C1, is thought to be a partially proteolysed BChE that is missing the 40 residue-tetramerization domain at the BChE C-terminal.

BChE from human, rhesus monkey, horse, cat, tiger, guinea pig, and mouse resolved into monomer, dimer and tetramer bands on the nondenaturing gels in Fig. 3A, whereas BChE from rabbit, rat, and chicken merely showed tetramer bands. Minor BChE bands are probably present in the plasma of rabbit, rat, and chicken, but their concentration is below the limit of detection. The dominant form of BChE in human, monkey, horse, cat, tiger, rabbit, mouse, rat, and chicken plasma is a tetramer. However, the dominant form of BChE in guinea pig plasma is a dimer. Bands of BChE activity in human, monkey, horse, and mouse plasma that migrate more slowly than the BChE tetramer C4 are called storage bands because they are not present in freshly drawn plasma, but appear in plasma that has been stored.

Incubation of plasma with monoclonal B2 18–5 in Fig. 3A shifted the bands of BChE activity to slower migrating forms that represent a complex of BChE with antibody. Band shifts are clearly visible for human, monkey, horse, and cat plasma incubated with B2 18–5 (Fig. 3A lanes 2, 4, 6, 8), but are less evident for tiger plasma (Fig. 3A lane 10). The BChE band for rabbit plasma disappeared in the sample incubated with B2 18–5 (Fig. 3A lane 12). In contrast, band shifts are not seen for B2 18–5 incubated with plasma from pig, guinea pig, mouse, rat, chicken and cow, supporting the conclusion that B2 18–5 does not bind to BChE from these species. The nondenaturing gel in Fig. 3A supports the Pansorbin and Dynabeads results for monoclonal B2 18–5 by visually demonstrating the interaction of antibody with BChE from selected species.

The gel in Fig. 3A was counterstained with alpha-naphthylacetate and Fast Blue RR to reveal carboxylesterase activity in Fig. 3B. Carboxylesterase activity (CES) is seen as a dark green band above albumin. Horse, cat, tiger, rabbit, guinea pig, mouse, and rat have carboxylesterase in plasma, but human, monkey, pig, chicken, and cow have no carboxylesterase in plasma.

Binding of 3E8 to chicken BChE is visualized in Fig. 4 where the band for chicken BChE in lane 3 disappears following incubation with 3E8 (lane 4). The chicken BChE complex with 3E8 is assumed to have become too large to enter the gel. In contrast, incubation of chicken plasma with monoclonal B2 18–5 (Fig. 3A lane 22) had no effect on the mobility of chicken BChE, supporting the conclusion that chicken BChE does not bind to B2 18–5. BChE activity bands in human plasma shift to slower migrating forms following incubation with 3E8 (Fig. 4 lane 2); the broad smear of BChE activity in the stacking gel (Fig. 4 lane 2) indicates that the human BChE complex with 3E8 is heterogeneous and very large.

Table 2 compares the reactivity of monoclonals B2 18–5 and mAb2 with BChE in the plasma of 12 species as measured in 3 different assays.

3.3. BChE amino acid sequence comparisons

We used BLASTP 2.2.30 + to compare the protein sequence of human BChE with BChE from rhesus monkey, horse, cat, Bengal tiger, rabbit, pig, guinea pig, mouse, rat, chicken, and cow. The BLAST analysis revealed sequence identities of 72–96% (Table 3).

The BChE sequences of twelve species were aligned in Supplementary Fig. S5. Residues important for enzyme hydrolysis are present in all species. The low plasma BChE activity in some

Fig. 2. Reactivity of anti-HuBChE monoclonal antibodies with BChE in the plasma or sera from various animal species. A) measured with Pansorbin cells; B) measured with Dynabeads protein G.

species could be the consequence of amino acid sequence differences in regions not recognized as being important for catalysis or stability. Differences in the promoter and in the sequence around the translation start site could also explain low plasma BChE

activity.

Amino acid sequence identity does not predict which animal BChE will be recognized by monoclonal antibodies to human BChE. For example, though horse BChE and bovine BChE protein

Fig. 3. Nondenaturing polyacrylamide gradient gels of plasma/serum incubated without or with monoclonal B2 18–5, indicated by – without and by + with B2 18–5. A) stained for BChE activity with butyrylthiocholine iodide; B) counterstained with alpha-naphthylacetate and Fast Blue RR to reveal carboxylesterase activity (CES) and albumin. The arrow indicates the direction of migration toward the anode. The minor components of human plasma BChE are used as markers, where C1 is monomeric BChE, C2 is a dimer composed of one BChE subunit covalently bound to one albumin molecule, C3 is a BChE dimer, and C4 is the BChE tetramer.

sequences are 90% identical to human BChE, monoclonal B2 18–5 binds horse BChE but not bovine BChE.

4. Discussion

4.1. Mammals with very low BChE activity in plasma

All the animals in the present study have one BCHE gene and mRNA encoding the BChE protein. BChE activity varies 100-fold from a low of 0.05 U/ml in rat to 5.0 U/ml in rhesus monkey plasma. A similar species difference in plasma BChE activity was reported by Augustinsson, who assayed activity with butyrylcholine by the Warburg method [26]. Plasma of cow, goat and sheep had barely detectable levels of BChE activity, while plasma of rabbit, rat and swine had slightly higher but still 20-fold lower BChE activity compared to human plasma.

A generally accepted function of BChE is to detoxify poisons that are eaten or inhaled. Animals with the lowest plasma BChE levels might be expected to have compensating plasma carboxylesterase activity. Rabbit and rat have carboxylesterase in plasma, but pig, chicken, and cow have no carboxylesterase in plasma. Another function of BChE is hydrolysis of the neurotransmitter acetylcholine. BChE acts as an independent and complementary modulator of acetylcholine levels at the mouse neuromuscular junction [27].

4.2. Monoclonal antibodies that recognize BChE in animal plasma

Monoclonal antibodies B2 18–5 and B2 12–1 were created by

Brimijoin et al. in mouse against human BChE [19]. They tested their monoclonal antibodies in the Pansorbin assay for ability to bind BChE in the plasma of various species and found that B2 18–5 binds BChE in human, squirrel monkey, dog, cat, and horse plasma, but does not bind BChE in guinea pig, chicken and rat plasma. B2 18–5 was weak in binding BChE in rabbit plasma. B2 12–1 bound only human BChE. In a second study, B2 12–1 bound serum BChE in higher primates in the order of affinity by species: man > chimpanzee = pygmy chimpanzee > gorilla >> orangutan > gibbon [28] with Kd values ranging from 2.8 nM to 74 nM. In contrast, B2 18–5 discriminated only marginally between the BChE of apes and man [28].

The B2 18–5 monoclonal we tested was expressed in Chinese Hamster Ovary cells. The B2 12–1 monoclonal was expressed in human HEK 293 cells. Our results agree with those of Brimijoin et al. [19]. In conclusion the B2 18–5 and B2 12–1 monoclonal antibodies produced by recombinant DNA methods have the same species specificity as the monoclonal antibodies secreted by mouse hybridoma cells.

Monoclonal mAb2 was created in mouse against human BChE [20]. Similar to B2 18–5, monoclonal mAb2 has broad species specificity. Pairing analysis on the Octet Red96 system showed that mAb2 and B2 18–5 bind to overlapping but not identical epitopes on HuBChE [16]. B2 18–5 paired with mAb2 when B2 18–5 was the capture antibody, but not in the reverse format when mAb2 was the capture antibody. The observation that mAb2 binds to an epitope that is not completely identical to the epitope recognized by B2 18–5 justifies our finding that their species specificities have some

Fig. 4. Chicken BChE binds monoclonal antibody 3E8. Plasma (5 μ L) was incubated without or with monoclonal 3E8 (10 μ L), indicated by – without and by + with 3E8. Following incubation, the samples were subjected to nondenaturing gradient gel electrophoresis. The gel was stained for BChE activity. Lane 1, human plasma. Lane 2, human plasma +3E8. Lane 3, chicken plasma. Lane 4, chicken plasma +3E8. The 4% stacking gel contains a large-sized complex of human BChE and 3E8 (lane 2).

differences. Monoclonal mAb2, but not B2 18–5, binds BChE in the plasma of cow and pig.

None of the monoclonal antibodies in the present report recognized mouse BChE. A unique strategy for producing anti-mouse BChE antibodies in mice was introduced by Hrabovska et al. [18]. They immunized BChE knockout mice with recombinant mouse BChE and obtained highly efficient monoclonal antibodies that bind mouse BChE with Kd values in the nanomolar range [15]. No other laboratory has generated a monoclonal to mouse BChE.

4.3. Carboxylesterase in rabbit plasma hydrolyzes butyrylthiocholine

Rabbit plasma has two prominent bands of butyrylthiocholine hydrolase activity on a nondenaturing gel. The band near the top of the separating gel is BChE (P21927 UniProtKB). The band that migrates far into the gel is rabbit plasma carboxylesterase (CES). As a general rule carboxylesterases hydrolyze neutral esters but not positively charged esters. The carboxylesterase in rabbit plasma is an exception because it hydrolyzes the positively charged butyrylthiocholine. A previous report named the rabbit plasma carboxylesterase “monomeric BChE” [29]. However, Jbilo et al. concluded that “monomeric BChE” in rabbit plasma is carboxylesterase [30]. The rabbit plasma carboxylesterase did not bind to procainamide-affinity gel, it was not inhibited significantly by the specific BChE inhibitors eserine and iso-OMPA, and it preferred indoxyl acetate as a substrate. The existence of only one BCE gene in the rabbit genome means there is no support for two pharmacologically distinct BChE proteins.

Our results support the conclusion of Jbilo et al. [30] that the butyrylthiocholine hydrolase that migrates adjacent to albumin in Fig. 3 (lanes 11 and 12) is rabbit carboxylesterase. The carboxylesterases in horse, cat, tiger, rabbit, guinea pig, mouse, and rat plasma consistently migrate adjacent to albumin and stain with alpha-naphthylacetate. Bahar et al. also agreed that this second band of butyrylthiocholine hydrolase activity is the activity of rabbit carboxylesterase [31]. We found that monoclonal antibodies B2 18–5 and mAb2 shifted the position of rabbit BChE, but not rabbit CES, supporting the conclusion that the butyrylthiocholine hydrolase labeled BChE in Fig. 3 lanes 11 and 12 is BChE, while the band labeled CES is carboxylesterase.

Additional support for our conclusion that CES in Fig. 3 lanes 11 and 12 is carboxylesterase comes from studies of the hereditary deficiency of atropine esterase in rabbits. Rabbits deficient in atropine esterase do not have a band of butyrylthiocholine hydrolase activity adjacent to albumin on a nondenaturing gel [30]. The atropine esterase in rabbit serum is a carboxylesterase with a molecular weight of 65,000, similar to the molecular weight of albumin. The purified atropine esterase (carboxylesterase) has low but detectable activity with the positively charged esters acetylcholine, butyrylcholine, and benzoylcholine [32]. Carboxylesterases from rabbit liver also hydrolyze butyrylthiocholine though activity is detected only with 10–100 mM butyrylthiocholine concentrations and not with the 1 mM concentration that is standard for BChE activity assays [33]. Carboxylesterases are encoded by multiple genes. The NCBI database lists 25 genes for rabbit carboxylesterases all located on adjacent sites within chromosome 5-NC_013673.1. The carboxylesterase in rabbit plasma is encoded by a different gene than the carboxylesterases in rabbit liver.

Table 2
Species specificity of monoclonal antibodies B2 18–5 and mAb2 for BChE assayed on Pansorbin, Dynabeads, and nondenaturing PAGE.

	Pansorbin B2 18-5	Dynabeads B2 18-5	PAGE B2 18-5	Pansorbin mAb2	Dynabeads mAb2	PAGE mAb2
Human	++	++	++	++	++	++
Monkey	++	++	++	++	++	++
Horse	++	++	++	++	++	++
Cat	++	++	++	++	++	++
Tiger	++	+	+	++	+	+
Rabbit	+	+	+	+	+	–
Pig	–	–	–	++	+	–
Guinea pig	–	–	–	–	–	–
Mouse	–	–	–	–	–	–
Rat	–	–	–	–	–	–
Chicken	–	–	–	–	–	–
Cow	–	–	–	++	+	–

++ indicates strong binding; + weak binding; – no binding to monoclonal.

Table 3

BChE protein sequence identities of various species.

Species	NCBI ^a	Swiss Prot ^a	Amino acids	Identity %
Human (<i>Homo sapiens</i>)	AAA98113	P06276	602	100%
Rhesus Monkey (<i>Macaca mulatta</i>)	AFE79500.1	–	602	96%
Horse (<i>Equus caballus</i>)	AAF61480.1	Q9N1N9	602	90%
Cat (<i>Felis catus</i>)	AAC06261.1	O62760	602	87%
Bengal Tiger (<i>Panthera tigris tigris</i>)	AAC06262.1	O62761	602	87%
Rabbit (<i>Oryctolagus cuniculus</i>)	XP_002716414.1	P21927	601	91%
Pig (<i>Sus scrofa domestica</i>)	XP_003358712.1	–	602	89%
Guinea Pig (<i>Cavia porcellus</i>)	XP_003469406.1	H0V4F8	602	83%
Mouse (<i>Mus musculus</i>)	AAA37328.1	Q499C7	603	80%
Rat (<i>Rattus norvegicus</i>)	NP_075231	Q9JKC1	597	80%
