Site Preparation: Key to Successful Conservation Tree Planting in Western Nebraska

Doak Nickerson, District and Extension Forester

This NebGuide explains when and how to do site preparation for conservation tree planting in Western Nebraska.

Benefits of Site Preparation

Establishing a conservation tree planting can be a challenge in semiarid regions like western Nebraska, where annual precipitation of 20 inches or less is the norm. Tree planting failure commonly occurs as a result of poor site preparation coupled with inadequate weed and grass control the first three to five years after planting. Effective site preparation (Table I) begins the year before planting. The results help young trees survive and grow in several ways:

- Increases the soil moisture needed for firm compaction, thereby reducing the risk of air pockets drying out and killing tree roots;
- Reduces present and future weed and grass competition, resulting in extra soil moisture, nutrients and sunlight for trees;
- Conditions and mellows the soil, making it easier to plant trees by machine and/or hand;
- Improves the effectiveness of follow-up weed and grass control practices; and
- Enhances rodent control measures which deter feeding damage on trees.

This is evident by the growth difference of two 10-year-old Rocky Mountain juniper trees (Figures 1 and 2), both planted on the same date and site in western Nebraska (Sioux county). Figure 1 was planted directly in grassland (sod) with no advance site preparation. Figure 2 was planted in a section of the grassland site that had been fallowed one full year before tree planting. The growth rate of Figure 2 is triple that of its counterpart, which is clear evidence that advance planning and excellent site preparation (fallow) help lead to success. Fallowing is a common farming practice in semiarid regions that has proven to be the “secret” in getting a new tree planting off to a good start.

*Area(s) defined as 6 to 8 feet wide strip(s), circle(s) and/or square(s) with tree(s) centered and planted in the area(s).

Figure 3. Machine tree planting in cropland (wheat stubble residue).

Figure 4. Trees planted in cropland (6 to 8 feet wide strips of wheat killed with postemergence herbicide prior to planting).
Clay/Loam (moist) will form a “ribbon” that does not crumble when squeezed between the forefingers and thumb. They are commonly referred to as “heavy” soils.

Sand (moist) will form a “ribbon” that crumbles when squeezed between the forefinger and thumb. It is sometimes referred to as “light” soil.

If cool season annuals (weeds, grasses and/or crops like wheat, oats, triticale, rye, barley) are beginning to grow in early spring prior to planting, till the site/area(s) “lightly” and/or treat with labeled, preemergence and/or postemergence herbicide** to conserve crop residue.

Check for herbicide carryover via farm records and/or soil analysis. Delay (one year) planting into cropland that has been treated with non-labeled, residual, soil active herbicide and/or treat the area(s) with labeled, preemergence and/or postemergence herbicide** to conserve dead grass residue.

Fallow is done one full year prior to planting, whereby the ground is tilled, mulched and/or herbicide** treated to eliminate soil moisture loss from weed/grass growth and preserve it for new tree seedlings. A tree planting that is fallowed by mulching with man-made fabric (Figure 9) is limited to follow-up hand planting, only.

Fallow mechanically (“light” tillage or wide scalping), soil surface mulch (organic or man-made fabric) and/or chemically (no-till) with labeled, preemergence and/or postemergence herbicide** to conserve dead grass residue.

If cool season, annual weeds/grasses are beginning to grow in early spring prior to planting, till the site/area(s) “lightly”, apply new layer of mulch (organic) and/or treat with labeled, preemergence and/or postemergence herbicide** to conserve dead grass residue.

Fallow via soil surface mulch (organic or man-made fabric) and/or chemically (no-till) with labeled, preemergence and/or postemergence herbicide** to conserve dead grass residue.

If cool season, annual weeds/grasses are beginning to grow in early spring prior to planting, apply new layer of mulch (organic) and/or treat the area(s) with labeled, preemergence and/or postemergence herbicide** to conserve dead grass residue.

Scalping removes soil surface residue for more efficient planting, reduces competition for soil moisture from unwanted weeds/grasses, creates water/snow catchment area(s) and provides some wind protection. It is accomplished mechanically by two methods:

• Wide scalping of an area (6 to 8 feet wide, 3 inches deep) via motor grader or large farm blade; soil/sod is scalped off to the upwind side followed by deep tillage/roughening of the area(s) one year ahead of planting, leaving a windrow of soil/sod to catch winter snow; prior to planting in spring, windrow of soil and dead sod is spread back out over the 6 to 8 feet wide fallow area(s) via grader/blade.

• Narrow scalping of a furrow (12 inches wide, 3 inches deep) via two small plow share attachments (scalpers) that mount on both sides of the tree planting machine’s coulter wheel, scalping the soil and dead sod residue as trees are planted.

Scalping also can be done manually with the tree centered and hand planted in a circular basin (12 inches wide, 3 inches deep) built with a shovel.

Hardpan may be present as a result of farming, overgrazing by livestock, heavy vehicle traffic and/or soil geology. This is especially true of clay or loam soils. Check for hardpan by pushing a slender metal rod into “moist” soil; if the rod is hard to push or stops abruptly, then hardpan may exist. Confirm this by hand digging a hole with a shovel. Break up the hardpan with deep tillage (12 to 24 inches) one year prior to planting via use of a chisel, subsoiler or ripper/scarifier (Figure 10).

**Refer to the latest University of Nebraska Cooperative Extension Circular titled Guide for Weed Management in Nebraska EC-130; determine appropriate use and application of herbicide(s) for site preparation before the planting plan is developed and trees are planted.
