### ACKNOWLEDGMENT

This circular is a progress report of grain sorghum trials conducted to obtain yield and other information for some of the sorghum hybrids and varieties which have been developed. The 1979 season was the 22nd that private hybrid strains were included in extensive trials. Seed producers supported tests through payment of fees.

Cooperating in this project were the Agronomy Department and the South Central, North Platte, and Panhandle Stations. Acknowledgment is made to County Extension Agents and others who assisted in these tests. Special acknowledgement is made to farmer cooperators and to W.M. Ross, S.E.A., U.S.D.A. sorghum breeder. Conduct of experiments and publication of results is a joint effort of the Agricultural Experiment Station and the Cooperative Extension Service

## NEBRASKA GRAIN SORGHUM PERFORMANCE TESTS

1979

A. F. Dreier, P. T. Nordquist, L. V. Svec, P. H. Grabouski and L. A. Nelson <sup>1/</sup>

Nebraska produced a record 79 bushels per acre (4960 kg/ha) average grain sorghum yield in 1979. The 1,830,000 acres (741,150 ha) harvested was the same as in 1978. This was the lowest harvested acreage since 1972.

This circular is a progress report of grain sorghum trials conducted by the Agricultural Experiment Station. Harvest data were obtained from five of the six planted trials. Testing zones and locations of the tests are shown on the map (Page 3) and names of cooperators are included in Table A.

Names and addresses of entrants are shown in Table B. A list of entries and zones where tested are included in Table C. Selection of hybrids for each zone was made by the entrants. Entries are listed alphabetically by brand name and hybrid designation. Open-pedigree hybrids were entered by The Nebraska Agricultural Experiment Station.

Parentage of open-pedigree entries follows:

Martin	(Variety or line)
NB 505	Martin x NB 3494
RS 455	M-A4 x SD 104
RS 626	Tx 3197 x Tx 414
RS 671	Redlan x Tx 415
SD 106	(Variety or line)
TAM 680	Tx 378 x TAM 428

Data on one half bloom were obtained by visiting plots on alternate days during the flowering period. Where included, grain moisture determinations were made at or before harvest at a time when differences between entries were relatively high. This gives an indication of relative grain drying rates.

Plant height and head exertion readings were made at harvest. Lodging readings in 1979 were taken at or before harvest. In previous years, readings sometimes were taken after harvest. Reported yields are based on 56 pounds per bushel and 14% grain moisture.

Entries in the data tables are listed in order of increasing days from planting to one-half bloom. Days to bloom for all tests in the zone was used as the basis rather than individual trials. There are variations in maturity among trials and over years. The maturity of a hybrid is an important consideration in its evaluation for a given location. In making yield comparisons, hybrids should be compared with those having similar maturities.

Variations in soil fertility, moisture conditions and other factors are found in each test area. This makes it impossible to measure yielding ability of hybrids with absolute accuracy. For this reason, small yield differences have little meaning. A statistical measure of differences required for significance is given in each table. These differences were computed at the 5% and 25% levels of significance. At the 5% level, a difference of that magnitude would be expected once in twenty trials through chance alone. At the 25% level, a difference as large or larger would be expected by chance alone in one of four trials.

## RESULTS

The high average yield for the state indicates favorable weather conditions for grain sorghum in 1979. Summer months were generally cooler than average. The crop was behind normal in late summer. Above-normal September temperatures and late frost allowed later-maturing entries to mature.

The average performance of all entries at each test location is shown in Table D. Yields were especially high in Zone A. Lodging was high in Zone B. Zone C yields were high for this area.

The maturity-yield correlation ( $r$  value) is an indication of the relationship between maturity as measured by days to bloom and grain yield. In 1979, highly significant correlations between days to bloom and grain moisture were observed in two of three Zone A trials. Maturity and yield were not related in Lincoln County. In Cheyenne County, a highly significant negative correlation between maturity and grain yield was obtained. This indicates that later-maturing entries were lowest in grain yield. Even though the correlations were highly significant, they do not account for a major portion of the observed yield differences.

The average performance of entries included in trials over a five-year period is shown in Table E. These data show the effect of season on the characters measured. The same hybrids were averaged within each zone.

Zone A

One hundred one entries were grown at three Zone A locations in 1979. Average data are reported in Table 1a and individual location information from tests in Saunders, Franklin and Clay (irrigated) Counties are shown in Tables 1b, 1c and 1d respectively.

The Saunders and Clay County yields represent new high performance for these locations. Excellent nonirrigated yields also were obtained in Franklin County.

Later maturity as measured by days to bloom was correlated with higher grain yield in Saunders and Clay Counties. This relationship was nonsignificant in Franklin County. In nine of the last eleven years, later maturity was correlated with higher grain yield. Only in 1974, a very drouthy year, was earlier maturity related to higher grain yield. In 1971 there was no significant relationship between maturity and grain yield. Generally in south central and southeast Nebraska under favorable moisture conditions, the latest-maturing hybrids which mature before frost have given the highest grain yields. In seasons of severe moisture stress or early frosts, late hybrids were at a comparative yield disadvantage.

Period of years data for Zone A are given in Table 1e and 1f. Fifty four entries were included in two-year, 33 in three-year, 18 in four-year and 8 in five-year averages.

Zone B

No yield data were obtained from the trial in Hitchcock County. Early growing conditions were good in Lincoln County. The test was treated for grasshoppers in late June. Greenbug populations were heavy through August.

September was warm and dry. High temperatures (102° F) and heavy winds on September 8 placed plants under stress. Fall storms with wind and snow delayed harvest. Final harvest was completed in mid-December.

Final yields were near the five year average level (Table 2a). The combination of greenbugs, heat stresses and high winds with snow caused excessive stalk lodging. This was associated with Fusarium stalk rot infection.

Maturity was not related to grain yield in 1979. During the last eleven years, later maturity was significantly correlated with higher grain yield in four seasons, early maturity was related to lower yields in three seasons and there was no relationship between maturity and yield in three seasons. This gives an indication of the high year-to-year variability in relative performance of grain sorghums in southwest Nebraska.

Period of years data for Zone B are shown in Tables 2b and 2c. A total of 48 entries were included in two-year, 30 in three-year, 14 in four-year and 6 in five-year averages. Because of variability in hybrid performance over years, yield differences in three-and four-years averages were non-significant.

### Zone C

In Cheyenne County, early season moisture was good. Mid-summer moisture was short but temperatures were cooler than normal. September temperatures were much higher than usual. Most entries were green when killed by frost on October 4.

Final yields were much higher than the five-year average (Table 2a). There was a highly significant negative correlation between days to bloom and yield indicating that later maturity was accompanied by lower grain yield. This is usual at this location. In tests beginning in 1967, the 1977 season was the only exception to this trend. This indicates that the Panhandle of Nebraska requires earlier hybrids than areas further east at lower elevations. Cheyenne County (Zone C) has the same latitude as Saunders County (Zone A). Corresponding elevations are 4320 feet (1316 meters) at the High Plains Agricultural Laboratory and 1180 feet (360 meters) at the Mead Field Laboratory (Saunders County).

Period of years data for Cheyenne County are shown in Table 3b.

Measurement data in this circular are given in currently used U.S. units followed by the metric units in parentheses ( ). Some equivalents and conversions used are as follows:

1 centimeter	=	0.394 inches	cm	=	inches x 2.54
1 hectare	=	2.471 acres	ha	=	acres x 0.405
1 kilogram	=	2.205 pounds	kg	=	pounds x 0.454
1 hectoliter	=	2.838 bushels	hl	=	bushels x 0.352
1 metric ton	=	2,204.6 pounds	metric ton	=	tons x 0.9072

kilogram/hectoliter (kg/hl) = lb/bu x 1.287  
 Kilogram/hectare (kg/ha) = bu/A x 62.78 (56# bushel)  
 metric ton = bushels x 0.0254

Table D. Average performance at each test location. 1979. Grain sorghum.

Early grain moisture - Saunders County only.

Lodging - Franklin County only.

Metric conversion for head exsertion: 2.54 x in = centimeters.

Metric conversion for test weight: 1.287 x lb/bu = kilograms/hectare.

Metric conversion for head exertion: 2.54 x in = centimeters.

Metric conversion for test weight: 1.287 x lb/bu = kilograms/hectoliter.

## Agricultural Research for All of Nebraska

The agricultural research division of the Institute of Agriculture and Natural Resources is the Nebraska Agricultural Experiment Station. The Experiment Station relies on its research centers and field laboratories to provide applied knowledge for development of Nebraska's largest industry—agriculture. In addition, many Nebraska farmers cooperate by furnishing land and other facilities for research projects. This provides information from areas not well represented by stations.

The Cooperative Extension Service transmits data to users through District and County Ex-

tension Offices. Area and County Extension Agents are available to provide additional interpretation and more specific recommendations.

Nebraska is a large state and has great variation due to topography and the continental type of climate. The elevation ranges from 1,000 feet to near a mile high in the northwest portion of the state, rainfall varies from 14 to 40 inches per year, and the soil types vary from sands to heavy clays. The research program thus is broad in subject matter and geography, resulting in the need for various stations and satellite locations.

**The Cooperative Extension Service provides information and educational programs to all people without regard to race, color or national origin.**
