## ACKNOWLEDGEMENT

This circular is a progress report of grain sorghum trials conducted to obtain yield and other information for some of the sorghum hybrids and varieties which have been developed. The 1983 season was the 26th that private hybrid strains were included in extensive trials. Seed producers supported tests through payment of fees.

Cooperating in this project were the Agronomy Department and the South Central, North Platte, and Panhandle Stations. Acknowledgement is made to County Extension Agents and others who assisted in these tests. Special acknowledgement is made to farmer cooperators and to W. M. Ross, U.S.D.A. sorghum breeder. Conduct of experiments and publication of results is a joint effort of the Agricultural Experiment Station and the Cooperative Extension Service.

## NEBRASKA GRAIN SORGHUM PERFORMANCE TESTS

1983

A. F. Dreier, P. T. Nordquist, R. W. Elmore  
and L. A. Nelson <sup>1/</sup>

Recent grain sorghum acreages and yields in Nebraska were as follows:

	1977	1978	1979	1980	1981	1982	1983
Yield bu/A	71.0	75.0	79.0	60.0	80.0	73.0	59.0
Acres(000)	2,070	1,830	1,830	2,030	2,060	1,670	1,080

Nebraska had a cold wet spring. This delayed grain sorghum planting. On May 10 only 10% of the crop was planted. Normal for this date is 30% planted. On June 1, planting was 35% compared to an average of 60% completion. Early June planting proceeded rapidly and planting was 93% complete on June 14.

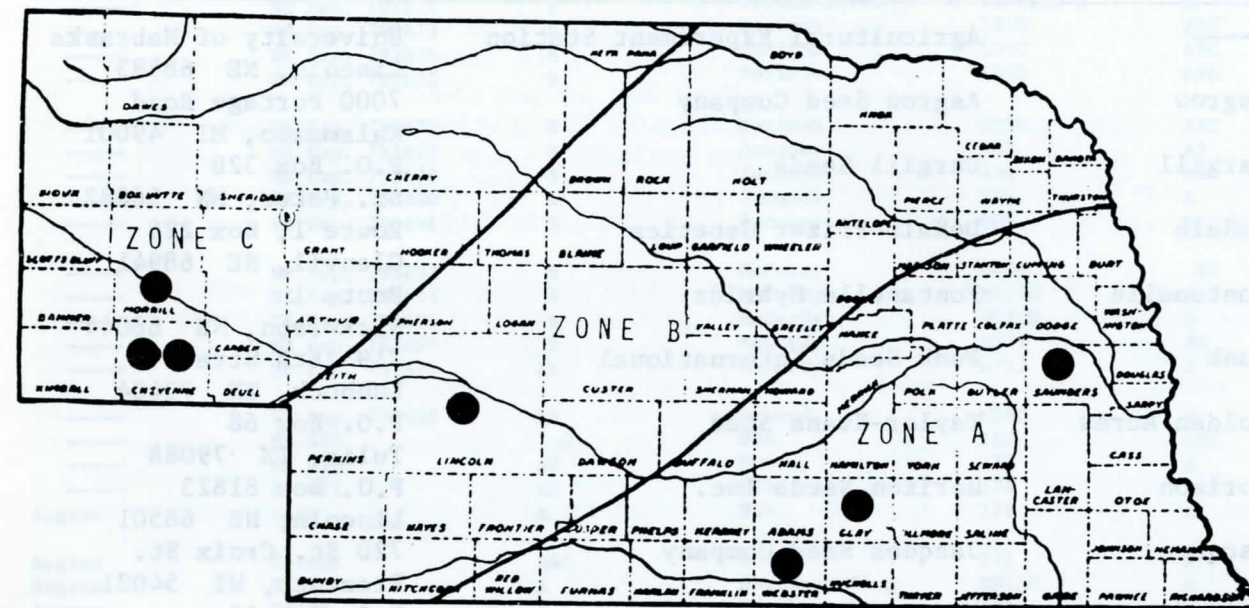

June was cooler than normal with above average precipitation. July temperatures ranged from two degrees above normal in the West to four degrees above in the East. Precipitation ranged from 25% of average in the Southeast to 150% in the Sandhills. Early heading was delayed, but by mid-August development was only 5% behind.

August average temperatures ranged from +4 degrees in the West to +8 degrees in the East. Rainfall ranged from 100% of usual in the West to 25% in the East. Grain sorghum made rapid progress. Maturity was ahead of normal. Harvest proceeded rapidly. On October 11, 50% of the crop was out of the field. Normal completion for this date is 25%.

This circular is a progress report of grain sorghum trials conducted by the Agricultural Experiment Station. Testing zones and locations of the trials are shown on the map (Page 3) and names of cooperators are shown in Table A. Data from Franklin and Morrill Counties are not reported because of extreme plot variability resulting from uneven stands and other complications.

Names and addresses of entrants are shown in Table B. A list of entries and zones where tested are included in Table C. Selection of hybrids for each zone was made by the entrants. Entries are listed alphabetically by brand name and hybrid designation. Open-pedigree hybrids were entered by the Nebraska Agricultural Experiment Station.

<sup>1/</sup> Agronomists; Agricultural Experiment Station, Lincoln; North Platte Station, North Platte; South Central Station, Clay Center; and Panhandle Station, Scottsbluff, respectively.

Parentage of released open-pedigree entries follows:

Martin	Variety or line
RS 455	M-44 x SD 104
RS 626	Tx 3197 x Tx 414
RS 671	Redlan x TX 415

Data on one half bloom were obtained by visiting plots on alternate days during the flowering period. Where included, grain moisture determinations were made at or before harvest at a time when differences between entries were relatively high. This gives an indication of relative grain drying rates.

Plant height and head exertion readings were made at harvest. Lodging readings were taken at harvest. In previous years, readings sometimes were taken after harvest. Reported yields are based on 56 pounds per bushel and 14 percent grain moisture.

Entries in data tables are listed in order of increasing days from planting to one half bloom. There are variations in maturity among trials and over years. The maturity of a hybrid is an important consideration in its evaluations for a given location. In making yield evaluation, hybrids should be compared with those having similar maturities.

Variations in soil fertility, moisture conditions and other factors are found in each test area. This makes it impossible to measure yielding ability of hybrids with absolute accuracy. For this reason, small yield differences have little meaning. A statistical measure of differences required for significance is given in each table. These differences were computed at the 5 percent and 25 percent levels of significance. At the 5 percent level a difference of that magnitude would be expected once in twenty trials through chance alone. At the 25 percent level, a difference as large or larger would be expected by chance alone in one of four trials.

## RESULTS

The average performance of all entries at each 1983 test location is shown in Table D. The Saunders and Lincoln County trials were hand harvested. Others were machine harvested.

The maturity yield correlation (r value) is an indication of the relationship between maturity (as measured by days to bloom) and grain yield. In Zone A, later bloom was correlated with higher grain in two trials. In Zones B and C, earlier maturity was correlated with higher grain yields. This relationship was especially high in the ecofallow trial. The average performance of hybrids included in trials over a five-year period is shown in Table E. These data indicate the effects of years on the characters measured.

### Zone A

Seventy-seven hybrids were grown at three Zone A locations in 1983. The Webster County data were discarded because of extreme plot variability. Average data for Saunders and Clay Counties are shown in Table 1a and individual location results are included in Tables 1b and 1c. Period-of-years data are shown in Tables 1d, 1e and 1f.

The Saunders County Trial was under moisture stress in August and early September. Clay County yields were not as high as would be desirable under full irrigation. Later maturity was correlated with higher yield at both locations. These relationships were not high enough to account for a major portion of hybrid differences. In 13 of the last 15 years, later maturity was correlated with higher yield in Zone A trials. In 1974, a very drouthy year with cooler than normal August and September temperatures, earlier maturity was accompanied by higher grain yield. In 1971 there was no relationship between these factors.

### Zone B

Data from Lincoln County are shown in Table 2a. Excellent yields were produced in 1983. High temperatures in mid-August greatly reduced corn yields at this location. Later maturity was correlated with lower yields. Data from 1978-1983 trials are summarized in Tables 2b and 2c. In 15 years of trials in southwest Nebraska, later maturity was correlated with higher grain yield in 5 seasons, earlier maturity was correlated with higher grain yield in 5 seasons and there was little relationship in 5 seasons. This is in an area of high year to year variability in climatic conditions.

### Zone C

A total of 31 entries were planted in Cheyenne County on black fallow and ecofallow (Tables 3a, 3b and 3c). Average yields were 75.2 and 56.5 bushels per acre, respectively. The ecofallow trial was planted 18 days later; however, the average bloom date was only 3 days later. Later maturity was correlated with lower grain yield. A limited number of entries are included in 2-, 3-, 4- and 5-year averages (Table 3d). In tests since 1977, earlier maturity was correlated with higher grain yield in 1978, 1979 and 1983. There was no relationship in 1977, 1980 and 1981. No data were obtained in 1982.

Data from an irrigated trial in Morrill County were discarded because of uneven stands.

## THE METRIC SYSTEM

Some equivalents are as follows:

1 centimeter	= 0.394 inches	cm	= inches x 2.54
1 hectare	= 2.471 acres	ha	= acres x 0.405
1 kilogram	= 2.205 pounds	kg	= pounds x 0.454
1 hectoliter	= 2.838 bushels	hl	= bushels x 0.352

Kilogram/hectoliter (kg/hl) = lb/bu x 1.287

Kilogram/hectare (kg/ha) = bu/A x 62.78 (56# bushel)

Table D. Grain sorghum performance. Average performance at each test location. 1983.

Location	Planted	Seed spacing inches <sup>1/</sup>	Planting to bloom days	Plant height inches	Head exsertion inches	Test weight lb/bu	Grain yield bu/A	Yield C. V. %	Maturity yield correlation r
Zone A (77 entries)									
Saunders	May 28	3.3	71.0	41.3	3.6	56.8	102.7	9.7	.34**
Clay (irrigated)	May 26	2.2	74.5	49.0	4.2	54.9	117.8	10.3	.25*

# Agricultural Research for All of Nebraska

The agricultural research division of the Institute of Agriculture and Natural Resources is the Nebraska Agricultural Experiment Station. The Experiment Station relies on its research centers and field laboratories to provide applied knowledge for development of Nebraska's largest industry—agriculture. In addition, many Nebraska farmers cooperate by furnishing land and other facilities for research projects. This provides information from areas not well represented by stations.

The Cooperative Extension Service transmits data to users through District and County Ex-

tension Offices. Area and County Extension Agents are available to provide additional interpretation and more specific recommendations.

Nebraska is a large state and has great variation due to topography and the continental type of climate. The elevation ranges from 1,000 feet to near a mile high in the northwest portion of the state, rainfall varies from 14 to 40 inches per year, and the soil types vary from sands to heavy clays. The research program thus is broad in subject matter and geography, resulting in the need for various stations and satellite locations.

**The Cooperative Extension Service provides information and educational programs to all people without regard to race, color, national origin, sex or handicap.**
