This study presents the structural and magnetic properties of melt-spun HfCo₇, HfCo_{7-x}Fe_x (0.25 ≤ x ≤ 1), and HfCo₇Si_x (0.2 ≤ x ≤ 1.2) alloys. Appreciable permanent-magnet properties with a magnetocrystalline anisotropy of about 9.6–16.5 Mergs/cm³, a magnetic polarization $J_s \approx 7.2$ –10.6 kG, and coercivities $H_c = 0.5$ –3.0 kOe were obtained by varying the composition of these alloys. Structural analysis reveals that the positions of x-ray diffraction peaks of HfCo₇ show good agreement with those corresponding to an orthorhombic structure having lattice parameters of about $a = 4.719$ Å, $b = 4.278$ Å, and $c = 8.070$ Å. Based on these results, a model crystal structure for HfCo₇ is developed and used to estimate the magnetic properties of HfCo₇ using density-functional calculations, which agree with the experimental results.

Index Terms—Doping, magnetocrystalline anisotropy, permanent magnets, rare-earth-free alloys.

I. INTRODUCTION

RECENTLY, the search for rare-earth-free alloys with magnetocrystalline anisotropy $K_1 \geq 10$ Mergs/cm³ and magnetic polarization $J_s \geq 10$ kG ($J_s = 4\pi M_s$, M_s is saturation magnetization) has become the thrust area of permanent-magnet research, which is aimed at satisfying the rapidly growing demand for rare-earth elements and reducing the cost of the permanent magnets for bulk applications [1]–[3]. In this regard, the HfCo₇ intermetallic phase has shown high Curie temperature T_c (~600 K) and J_s (~10 kG), and is reported to form a non-cubic crystal structure, which can cause a high K_1 suitable for permanent-magnet applications [4]–[8]. However, according to Co-Hf binary phase diagram, the HfCo₇ phase forms only at a single composition (12.5 at. % of Hf) and temperatures above 1000°C under thermal equilibrium conditions [9]; thus it is challenging to control the phase purity and crystal structure, which is important to obtain permanent-magnet properties in HfCo₇. These limitations presumably restricted earlier studies on bulk HfCo₇ alloys, which do not provide a detailed structural analysis and other vital information such as magnetic anisotropies and coercivities [4]–[8].

In particular, the crystal structure of HfCo₇ is insufficiently known, with conflicting reports on unit cells (tetragonal, hexagonal or orthorhombic) and without information about individual atomic positions [4]–[7]. Recently, stoichiometric HfCo₇ nanoparticles were produced using a gas-aggregation-type cluster-deposition system. These nanoparticles have shown permanent-magnet properties with a $K_1 \approx 10$ Mergs/cm³ and $H_c \approx 4.4$ kOe at 300 K and their x-ray diffraction peaks could be indexed with an orthorhombic structure [10]. In the present study, we have investigated the structural and magnetic properties of melt-spun HfCo₇, HfCo_{7-x}Fe_x and HfCo₇Si_x

bulk alloys, and also proposed a model crystal structure for HfCo₇, which provides an opportunity to estimate the magnetic properties using density-functional calculations and new insights in understanding the underlying magnetic properties of HfCo₇-based alloys. Note that the rapid cooling during the melt-spinning process is advantageous in obtaining the phase purity and desired crystal structure in these alloys.

II. EXPERIMENTAL AND THEORETICAL METHODS

Ribbons of HfCo₇, HfCo_{7-x}Fe_x (0.25 ≤ x ≤ 1), and HfCo₇Si_x (0.2 ≤ x ≤ 1.2) were fabricated by melt spinning. For this, alloys with the above-mentioned nominal compositions were made from high purity (>99.95%) elements using conventional arc melting followed by melt spinning in high-purity argon atmosphere at a tangential wheel velocity of 40 m/s. Bulk ribbons were characterized using a superconducting quantum interference device (SQUID) magnetometer, energy dispersive x-ray spectroscopy (EDX, JEOL JSM 840A scanning electron microscope), and x-ray diffractometer (XRD, Rigaku D/Max-B diffractometer).

For model calculations, we use frozen-core full-potential projector-augmented-wave method as implemented in the Vienna *Ab-Initio* Simulation Package (VASP) within the framework of density-functional theory (DFT) [11], [12]. The exchange and correlation effects are described by the method of Perdew, Burke and Ernzerhof using the generalized-gradient approximation (GGA) [13].

III. EXPERIMENTAL RESULTS

XRD patterns for HfCo₇, HfCo_{6.5}Fe_{0.5}, and HfCo₇Si_{0.4} are shown in Fig. 1. We have carried out the peak indexing analysis on the XRD pattern of HfCo₇ (curve i in Fig. 1) using TOPAS (Total Pattern Analysis Solution, Bruker AXS) by assuming all the reported crystal structures such as hexagonal, tetragonal or orthorhombic. The positions of the experimental XRD peaks of HfCo₇ (curve i in Fig. 1) show good agreement with the diffraction-peak positions determined using TOPAS (vertical lines in Fig. 1(a)) for an orthorhombic structure having lattice parameters of about $a = 4.719$ Å, $b = 4.278$ Å, and $c = 8.070$ Å.

Fig. 1. X-ray diffraction patterns for HfCo₇, HfCo_{6.5}Fe_{0.5}, and HfCo₇Si_{0.4}, where the XRD peak positions determined using TOPAS for orthorhombic structure are shown as vertical lines. A shift in the XRD peak positions of HfCo_{6.5}Fe_{0.5} as compared to those of HfCo₇ is guided by a vertical dotted line.

Fig. 1 also reveals that HfCo_{7-x}Fe_x and HfCo₇Si_x alloys have XRD patterns similar to HfCo₇ (curve i) as shown in the case of HfCo_{6.5}Fe_{0.5} (curve ii) and HfCo₇Si_{0.4} (curve iii). In addition, HfCo_{6.5}Fe_{0.5} exhibits a shift in the angular position of the diffraction peaks towards lower angle side (for example, as indicated by a dotted line in the case of (202) peak of HfCo_{6.5}Fe_{0.5}) as compared to HfCo₇ and this result reveals a lattice expansion on the substitution of Fe for Co in HfCo_{7-x}Fe_x. In the case of HfCo₇Si_{0.4}, the position of XRD peaks does not show considerable shift with respect to that of HfCo₇, presumably due to the interstitial occupation of Si in HfCo₇ lattice. Interestingly, alloying of HfCo₇ with Si improves the crystallinity of these alloys as revealed by the sharp diffraction peaks in the case of HfCo₇Si_{0.4}, as compared to HfCo₇ and HfCo_{6.5}Fe_{0.5}.

The magnetic properties of the HfCo₇, HfCo_{7-x}Fe_x, and HfCo₇Si_x alloys were investigated by measuring the magnetization (M) curves at 300 K as a function of applied magnetic field H from -70 to 70 kOe and show two important features. First, the expanded room-temperature $M-H$ curves from $H = -25$ to 25 kOe for HfCo₇, HfCo_{6.5}Fe_{0.5}, and HfCo₇Si_{0.4} show high H_c as shown in Fig. 2(a), as compared to $H_c \approx 0.09$ kOe for bulk hcp Co (not shown in Fig. 2(a)). Second, M does not attain complete saturation even at $H = 70$ kOe as shown by the $M-H$ curves in the high-field region (Fig. 2(b)) and this behavior indicates a large value of magnetic anisotropy in HfCo₇-based alloys. The magnetic anisotropy constant K_1 was estimated from the high field region of the experimental $M-H$ curves ($H > 30$ kOe) using the law of approach to saturation method, widely used for randomly oriented magnets [14]–[16].

$$M = M_s \left(1 - \frac{A}{H^2} \right) + \chi H \quad (1)$$

In (1), χ is the high-field susceptibility and the constant A depends on the anisotropy constant K_1 as given by

$$A = \frac{4}{15} \frac{K_1^2}{M_s^2} \quad (2)$$

The experimental M (solid spheres) in the high field region ($H > 30$ kOe) is fitted as represented by solid lines using (1) to estimate K_1 as shown in Fig. 2(b). This evaluation reveals high magnetic anisotropies of about 10 Mergs/cm³ in

Fig. 2. (a) The expanded $M-H$ curves from $H = -25$ to 25 kOe for HfCo₇, HfCo_{6.5}Fe_{0.5}, and HfCo₇Si_{0.4} alloys measured at 300 K (b) An estimation of magnetic anisotropy constant K_1 from the high-field region of room-temperature M vs. H curves ($H > 30$ kOe) using the law of approach to saturation method [14]–[16]. The solid spheres and lines represent the corresponding experimental data and fittings, respectively.

Fig. 3. The measured values of magnetic anisotropy constant K_1 and polarization J_s as a function of x in HfCo_{7-x}Fe_x and HfCo₇Si_x at 300 K.

HfCo₇-based alloys as indicated in Fig. 2(b). Note that the law of approach to saturation method yields $K_1 \approx 4.7$ Mergs/cm³ for bulk hcp Co (not shown here), but the magnetization of HfCo₇-based alloys is considerably reduced as compared to 1438 emu/cm³ of bulk hcp Co (not shown in Fig. 2(b)).

K_1 and J_s of HfCo_{7-x}Fe_x and HfCo₇Si_x as a function of x are summarized in Fig. 3. These results show that J_s improves on substituting Fe for Co in HfCo_{7-x}Fe_x, but K_1 exhibits a slight decrease for high $x \approx 0.75$ and 1 . In the case of HfCo₇Si_x, both K_1 and J_s decrease on increasing x . In brief, these results reveal that permanent-magnet properties of HfCo₇-based alloys can be tailored by varying the composition of these alloys.

IV. MODEL STRUCTURE AND ANISOTROPY CALCULATIONS

Our XRD analysis indicates that HfCo₇ has an orthorhombic unit cell with lattice parameters of $a = 4.719$ Å, $b = 4.278$ Å, and $c = 8.070$ Å. Based on these lattice parameters, the metallic radii of dense-packed Hf and Co atoms suggest two formula units in the unit cell, and thus this structure can be realized by an

Fig. 4. Structural models for HfCo₇, based on experimental lattice parameters: (a) Hard-core model (*xy*-planes for various *z*-values) and (b) atomic positions after relaxation using VASP.

atomic hardcore model in which Hf atoms are coordinated with Co atoms as shown in Fig. 4(a). DFT was used to relax the structure inside the unit cell, and Fig. 4(b) shows the corresponding atomic positions in HfCo₇. Note that Fig. 4(b) is a model structure aiming at an approximate description of the alloy during quenching, as monitored by XRD. Very likely, the equilibrium structure of HfCo₇ is different from Fig. 4(b), with complicated stackings of simple units such as that in Fig. 4(b). Further experimental and theoretical research is necessary to clarify these points.

The structure of Fig. 4(b) is used to calculate the magnetization and the magnetic anisotropy of HfCo₇, in the latter case using the energy difference method by including spin-orbital coupling in noncollinear mode [17], [18].

A rather unusual feature of the anisotropy and micro-magnetism of orthorhombic crystals is the existence of two lowest-order anisotropy constants, K_1 and K'_1 , defined by the anisotropy energy [19]

$$\frac{E}{V_{atom}} = K_0 + K_1 \sin^2 \theta + K'_1 \sin^2 \theta \cos 2\varphi \quad (3)$$

By solving (3) for three principle directions, the following equations are obtained

$$\frac{E_{001}}{V_{cell}} = K_0 \quad (\theta = 0^\circ, \phi = 0^\circ) \quad (4)$$

$$\frac{E_{100}}{V_{cell}} = K_0 + K_1 + K'_1 \quad (\theta = 90^\circ, \phi = 0^\circ) \quad (5)$$

$$\frac{E_{010}}{V_{cell}} = K_0 + K_1 - K'_1 \quad (\theta = 0^\circ, \phi = 90^\circ) \quad (6)$$

θ and ϕ are the magnetization angles with respect to *c* and *a* axes, respectively. The energy values $E_{100} = 0.00$ meV/f.u., $E_{010} = 1.67$ meV/f.u., and $E_{001} = 1.78$ meV/f.u obtained from the DFT calculations make it possible to extract the anisotropy constants from (4)–(6) as $K_1 = -16.46$ Mergs/cm³ and $K'_1 = -18.53$ Mergs/cm³, which are in the range of the experimentally measured $K_1 \approx 14.0$ Mergs/cm³ at 300 K for HfCo₇. Note that the two anisotropy constants give rise to a small rotational anisotropy (around *c*), but it is predominantly in-plane. The negative value of K_1 and K'_1 also suggests that HfCo₇ possibly has easy plane anisotropy. However, DFT calculations somewhat overestimate J_s (11.4 kG), as compared to the experimentally room-temperature value of J_s (8.9 kG). This difference can be attributed to the following facts: (i) the theoretical calculations are relevant to zero-temperature and (ii) the experimental magnetization does not saturate even for a field $H \approx 70$ kOe.

In addition, Hf atoms are coupled anti-ferromagnetically with the neighboring Co atoms. The spin and orbital moments of Hf in HfCo₇ are -0.32 and 0.011 μ_B /atom, respectively. This coupling reduces the average spin moment of Co in HfCo₇ to 1.08 μ_B /atom as compared to 1.6 μ_B /atom of bulk Co.

V. CONCLUSIONS

In conclusion, HfCo₇, HfCo_{7-x}Fe_x, and HfCo₇Si_x alloys were prepared using melt-spinning method and their structural and magnetic properties were investigated. X-ray diffractions of HfCo₇-based alloys were indexed with an orthorhombic structure having lattice parameters of about $a = 4.719$ Å, $b = 4.278$ Å and $c = 8.070$ Å. These studies show that high magnetic anisotropies ($K_1 > 10$ Mergs/cm³) and coercivities ($H_c \approx 3$ kOe) at 300 K can be obtained in HfCo₇-based alloys as compared to bulk hcp Co ($K_1 = 4.7$ Mergs/cm³ and $H_c = 0.09$ kOe). In addition, these alloys also exhibit appreciable magnetic polarization in the range of 7.2 to 10.8 kG. This study indicates that HfCo₇-based alloys are promising alternative alloys for permanent-magnets, from the view point of mitigating the critical material aspects of rare-earth permanent magnets.
