## Prudent Use of Antibiotics in Companion Animals

This NebGuide explains why antibiotics must be used with care and how to prudently use antibiotics to treat companion animals.

Antibiotics are used to improve animal health and performance. You, as the animal owner or caregiver, make important decisions about how antibiotics are finally used in companion animals. Antibiotics should be used prudently to ensure they are effective and will continue to benefit man and animals in the future. Are you prepared to make the best decisions about using antibiotics in animals?

### Why Do We Use Antibiotics in Animal Health?

One of the most easily recognized uses of antibiotics is to relieve illness and suffering in animals caused by bacterial infection. Antibiotics also are used to prevent infection when bacterial pathogens are suspected or known to be in the animal's environment or when an animal encounters high-stress situations that increase its susceptibility to infection and disease. Under these conditions antibiotics are given as a prophylactic because there is the reasonable expectation disease would occur if no action was taken.

The prudent use of antibiotics in food and companion animals may help minimize transmission of bacterial pathogens to humans. By minimizing bacterial infections in animals, antibiotics may reduce the opportunities for pathogenic bacteria to be transferred to people via direct contact with animals and/or consumption of animal products.

## **Why Should We Be Concerned About How We Use Antibiotics?**

Because of their importance to health and well-being, antibiotics have become a part of our daily existence. Consequently, animal caregivers may no longer give much thought to their use, and this leads to situations where antibiotics may get misused. When used appropriately antibiotics are a powerful tool for maintaining healthy animals. However, when antibiotics are used carelessly the consequences can be serious.

### *To Ensure Effectiveness*

One reason to use antibiotics prudently is to ensure that their use will benefit the animal being treated. Antibiotics are used to treat bacterial infections; if the condition for which the antibiotic is being administered is not the result of a bacterial infection, then the antibiotic will be of little or no use. In addition, even if the conditions are appropriate to use an antibiotic, it won't work as it should if it is used improperly, for example at the wrong dosage or for the wrong duration. It is costly to use an antibiotic inappropriately. The time spent using the wrong treatment delays making a correct diagnosis of the animal's condition and starting the correct therapy. Also, the health status of the animal may not improve and money will have been wasted on purchasing the drug.

### *To Prevent Selection for Antibiotic Resistant Bacteria*

Concern about selecting for antibiotic resistant bacteria is an important reason antibiotics should be used with care. Though not a new problem, concern about antibiotic resistance may affect the availability of animal medications in the future. Antibiotic use selects for bacteria that are resistant to the effects of antibiotics. When antibiotic is administered to an animal, it will kill or inhibit growth of all susceptible bacteria it encounters in the creature, not just those for which the antibiotic was given. Remaining are bacteria more resistant to the drug. These bacteria will no longer have to compete with the susceptible bacteria for space and nutrients within the host, enhancing their ability to survive and multiply. If these bacteria cause disease, the resulting infection may not respond to antibiotic treatment. Resistant bacteria share their resistance with other bacteria. In this way, it is possible for bacteria to gain resistance to an antibiotic it was never exposed to. Also, a bacterium may become resistant to multiple other antibiotics of similar structure or mechanism of action in a manner called cross-resistance. When antibiotics are not used appropriately, the opportunity for resistant bacteria to evolve increases needlessly and can compromise future antibiotic therapy.

## **Guidelines for Prudent Antibiotic Use**

The American Veterinary Medical Association (AVMA), and various veterinary practice specialty groups have developed guidelines for veterinarians on the prudent use of antibiotics in companion animals. These various guidelines are all based on providing the best care for the animal and protecting public health.

"When the decision is reached to use antimicrobials for therapy, veterinarians should strive to optimize therapeutic efficacy and minimize resistance to antimicrobials to protect public and animal health."

-AVMA Position on Judicious Antimicrobial Use, 1998

Often it is the animal owner or caregiver that decides how antibiotics will truly be used. Everyone who administers antibiotics to animals should understand and be willing to apply these general concepts of prudent use.

**1. Provide a system of care to prevent common diseases.**

It is more cost effective and beneficial to the animal's well-being to prevent disease than rely upon antibiotics to treat disease once it has developed. Minimizing disease risk is achieved by maintaining sanitation and hygiene, providing high quality food, providing protection from the elements, scheduling regular health exams and dentistry, and using vaccines and parasite control.

**2. When animals do get sick, have an accurate diagnosis.**

An accurate diagnosis is based upon clinical signs, history, lab data and past experience, and ensures antibiotics will be used for the appropriate clinical indications. Your veterinarian can help provide an accurate diagnosis of your animal's condition.

**3. Determine that antibiotics are the most appropriate option.**

Keep in mind the treatment outcomes you want for the animal and what types of therapy will help you achieve them. Will an antibiotic provide the results you want? Will the animal's condition even respond to antibiotics? Does the animal need only supportive therapy? Your veterinarian plays a key role in helping you answer these questions. Have your animal examined by a veterinarian for any condition for which you think antibiotics may be needed.

**4. Choose the most appropriate antibiotic for the circumstances.**

Not all antibiotics work the same and each acts against different types of bacterial infections. Culture and susceptibility tests of the causal organism will help determine the type of antibiotic most effective in clearing the infection. Select an antibiotic form that can be easily administered and will result in effective concentrations reaching the site of infection. When appropriate, use local therapy instead of systemic. Use only medications approved for the use you intend.

**5. Work with your veterinarian to enhance therapeutic options.**

Veterinarians have the knowledge and resources necessary to determine the most effective therapy for your animal. Your veterinarian can offer valuable guidance for the prudent use of over-the-counter antibiotics and, within the context of a valid Veterinarian-Client-Patient Relationship (VCPR, *Table I*), can offer enhanced therapy through the use of prescription and extra-label use medications. You must establish a valid VCPR with your veterinarian before receiving drug prescriptions or using an antibiotic any way other than exactly as labeled. This helps ensure your animal will receive medication that is both safe and effective at treating its condition.

**6. Use antibiotics as ordered.**

Follow the full treatment regimen. Do not stop treatment early, and unless directed to by your veterinarian, do not give leftover antibiotic to your animal for a future illness or to another animal for which the drug was not originally prescribed. Antibiotic therapy may not be as effective and can needlessly promote antibiotic resistance when not used as ordered.

**7. Treat the appropriate animals.**

Limit therapeutic antibiotic treatment to those animals that are sick or are legitimately at-risk of becoming sick.

**8. Store antibiotics and other medications appropriately.**

Drug integrity is maintained by following label and veterinarian instructions for proper handling, storage, and observation of expiration date. Mistakes in administering the wrong medication are less likely if drugs are clearly labeled and stored in the appropriate places, separate from human medicines.

**9. Minimize environmental contamination.**

Dispose of outdated medications according to label directions or veterinary advice. Use disposal methods that minimize contamination of soil and water supplies. Provide feed and water medication delivery so that there is minimal spillage into the environment.

#### **10. Use records to track treatments and evaluate outcomes.**

Keep accurate, detailed, and current records of antibiotic treatments and outcomes. Treatment records should include the identity of animals treated, dates treated, drugs administered, who administered the drugs, and the amount administered. Such information will keep you informed of the animal's health status, and is a useful supplement to veterinarian records.

---

#### **Table I. Valid Veterinarian-Client-Patient-Relationship.**

A veterinarian may only prescribe or direct extra-label use of antibiotics if a valid veterinarian-client-patient relationship (VCPR) has been established. In order for a valid VCPR to exist the following conditions must be met:

1. The veterinarian has assumed the responsibility for making clinical judgements regarding the health of the animal(s) and the need for medical treatment, and the client has agreed to follow the veterinarian's instructions.

2. The veterinarian has sufficient knowledge of the animal(s) to initiate at least a general or preliminary diagnosis of the medical condition of the animal(s). This means that the veterinarian has recently seen and is personally acquainted with the keeping and care of the animal(s) by virtue of an examination of the animal(s) or by medically appropriate and timely visits to the premises where the animal(s) are kept.

3. The veterinarian is readily available for follow-up evaluation, or has arranged for emergency coverage, in the event of adverse reactions or failure of the treatment regimen.

-Animal Medicinal Drug Use Clarification Act, 1996
