Short Notes

Second Record of *Myotis volans* from North Dakota

HUGH H. GENOWAYS

The first record of the long-legged myotis, *Myotis volans interior*, in North Dakota was reported by Jones and Genoways (Trans. Kansas Acad. Sci., 69:89, 1966) on the basis of a single male from 1 mi. S and 1 mi. W Medora, Billings County. On 25 May 1966, nine adult females (KU 106932-40) of this bat were obtained by Donald R. Johnson in Granville, McHenry County. These specimens extend the known geographic distribution of *M. v. interior* approximately 160 miles to the northeast from the previously reported North Dakotan locality and represent the northeasternmost locality of record for the species in North America.

The bats were captured in a mist net stretched along the eaves of a house. Johnson estimated that the attic of the house contained a colony of approximately 40 individuals. Because only females were netted, it is presumed that they represented an incipient maternity colony, but none of the specimens yet evidenced gross reproductive activity. Mean and extremes of length of forearm for the nine specimens, all preserved in spirits, are 37.9 (36.3-39.4) mm.
